This effect of relative acceleration is not exclusive of orbital movements; it also appears when particles move along the field lines (see Figure 8.2). Therefore, two "free" bodies having a same initial velocity with respect to the freely falling laboratory (spacecraft), for instance two bodies initially at rest relative to the laboratory, will undergo a relative acceleration; the larger the initial separation between the bodies, the larger their relative acceleration. This behavior affords an inner observer the possibility of detecting that he or she is in an accelerated laboratory in the presence of a gravitational field. In other words, if the gravitational field is not uniform then the inertial–gravitational field will not completely vanish in a freely falling laboratory. However, as the separation between the bodies decreases, the difference between a freely falling laboratory and a frame that could be called inertial becomes more negligible, since the right side in Eq. (8.3) decreases with the separation. Thus, it could be said that the cancellation of the inertial–gravitational field in a freely falling laboratory is a local property. A freely falling laboratory is *locally* indistinguishable from what is called inertial frame in Newtonian mechanics. In a freely falling laboratory the Principle of inertia is locally valid.

We shall raise these remarks about the local equivalence between gravitational forces and inertial forces to the rank of Principle. The *Principle of equivalence* will be the link between the laws of Physics in Special Relativity and what these laws should be in the presence of an inertial–gravitational field:

Principle of equivalence

> *At each event there exists a family of locally inertial frames where the laws of Physics adopt the known form they have in Special Relativity.*

The Principle of equivalence allows the existence of privileged "locally inertial" reference systems. In order that this privilege be admissible, the theory

Figure 8.2. Freely gravitating bodies that follow field lines. The relative acceleration is zero in a uniform gravitational field, but different from zero in a non-uniform field. The figures show positions separated by equal elapsed times.

describing the inertial–gravitational field should meet the spirit of Mach's Principle, in the sense that the inertial–gravitational field should be exclusively determined by the content of matter in the universe. In such a case, the privilege of locally inertial reference systems, which is conferred by the local cancellation of the inertial–gravitational field, will come from the relation between this kind of frames and the rest of the universe. Thus, the privilege will be then natural because it is dictated by the matter distribution in the universe, therefore contrasting with the artificial privilege of inertial frames in Newtonian mechanics and Special Relativity that is based on the state of absolute motion of the frames.

8.3. THE INERTIAL–GRAVITATIONAL FIELD

The formulation of the Principle of equivalence goes beyond the mechanical considerations supporting it. In fact, it intends non-mechanical phenomena—like light propagation—to be governed in a locally inertial frame by the same laws governing them in Special Relativity. In other words, the equivalence between gravitational and inertial forces is extended to electromagnetic phenomena: if we want to know how an electromagnetic field behaves in presence of gravity, then we can get a good indication by looking at the behavior of an electromagnetic field in an accelerated frame. The study of a couple of cases of this last kind will lead us to conclude that what we call inertial–gravitational field is just the manifestation of space-time geometric properties.

The first case to be considered is the propagation of a light ray in an accelerated frame. In the absence of gravity, classical physics predicts that the ray trajectory is rectilinear in any inertial frame; Special Relativity agrees with this description. It does not matter which is the chosen inertial frame; the trajectory will be rectilinear in any of them, because the transformation from one of them to any other involves a composition of two finite constant velocities, so it will result a constant velocity. The change of inertial frame produces a change of the propagation direction (aberration) but the rectilinear character of the ray is not altered. On the contrary, the transformation to an accelerated frame implies the composition of the ray uniform movement with the non-uniform movement characterizing the accelerated frame. Thus, the result is that the ray trajectory is not rectilinear in a non-inertial frame (see Figure 8.3). According to the Principle of equivalence, a similar effect has to produce a gravitational field: the inertial–gravitational field deflects the light rays. The inclusion of electromagnetic phenomena in the scope of the application of the Principle of equivalence leads to conclude that the electromagnetic energy gravitates.

the inertial–gravitational field deflects light rays

We shall now study how the frequency is affected by the inertial–gravitational field. Figure 8.4 shows an accelerated laboratory where a source is emitting light pulses of frequency ν_{src}. The pulses are received by a sensor at another place of the laboratory. Owing to the finite speed of light and the laboratory acceleration, when the pulses reach the sensor they find it in a state

Figure 8.3. The trajectory of a light ray is rectilinear in an inertial frame (left) but it bends in an accelerated frame (right).

of motion that is different from one of the source at the time of emission. In this way, the frequency ν_{obs} measured by the sensor will be different from ν_{src} as a consequence of Doppler effect (see §3.15). It does not matter that the sensor had acquired such a velocity difference while the pulses were traveling or that the relative velocity sensor-source had not changed since source and sensor are fixed to the same laboratory. Only the source velocity at the time of emission and the sensor velocity at the time of reception are relevant, because neither the source motion after the emission nor the sensor motion before the reception play any role in Doppler effect. Since the time elapsed when the pulses cover the distance H between source and sensor is $\Delta t = H/c$, then the velocity difference the sensor acquires with respect to the initial source velocity is $\Delta V = a\,\Delta t = a\,H/c$. According to Eq. (3.54), frequency ν_{obs} is

$$\nu_{obs} \cong \left(1 - \frac{\Delta V}{c}\right)\nu_{src} = \left(1 - \frac{a\,H}{c^2}\right)\nu_{src}$$

Figure 8.4. Light frequency undergoes a Doppler shift when is observed in an accelerated frame, because the frame velocity at the time of observation differs from the frame velocity at the time of emission.

so it is "redshifted" with respect to the source frequency. The Principle of equivalence forces us to accept that the same frequency shift will exist if the acceleration field is substituted by a gravitational field $\mathbf{g} = -\mathbf{a}$. In other words, the light frequency is redshifted when light "rises" a gravitational potential. Since the gravitational potential difference for a uniform field is $\Delta\Phi = gH$, then the gravitational frequency shift is

frequency redshifts when light rises a gravitational potential

$$\frac{\Delta \nu}{\nu} = \frac{\nu_{\text{obs}}}{\nu_{\text{src}}} - 1 \approx -\frac{\Delta \Phi}{c^2} \tag{8.6}$$

Frequency ν measures the energy of photons taking part in the luminous phenomenon. When a particle–antiparticle pair is created, two or more photons convert their energy into masses and kinetic energies of the created particles. Vice versa, in a pair annihilation the masses and kinetic energies of annihilated particles are converted into energy of the resulting photons. Since any mass has a gravitational potential energy which depends on the position occupied in the gravitational field, the light frequency must consistently vary when light propagates in a gravitational field, in order to avoid a violation of energy conservation by means of successive pair creation and annihilation. When photons rise a gravitational field, their frequency diminishes, also diminishing their capability for creating mass. But the created mass will benefit from the acquired gravitational potential energy.

As explained in §6.9, the frequency shift caused by the inertial–gravitational terrestrial field was measured by Pound and Rebka in 1960.

The light deflection due to the solar gravitational field was first observed by two expeditions sent from London to Sobral (Brazil) and Principe Island (a Portuguese possession in the Gulf of Guinea at that time, nowadays Republic of Saint Tome and Principe), on occasion of the total solar eclipse in 1919. The first of them was supervised by A. Crommelin and C. Davidson, while the second one was organized by A.S. Eddington and E.T. Cottingham. The total eclipse makes possible the observation of those stars whose light reaches the Earth going past close to the solar disc, where the solar gravitational deflection is more important. The deflection alters the line of vision to the star, thus displacing its site in the sky. Therefore, the deflection is determined by comparing the normal star location (when the Sun occupies another region in the sky) with the "displaced" location of the same star. The experiment was proposed by Einstein in 1911. The agreement between the performed measurements and the result predicted by 1915's General Relativity (see §9.3) definitively established Einstein's theory.[8]

See § 9.3

In this section we aim at glimpsing the kind of mathematical structure that could describe the inertial–gravitational field, explaining the gravitational deflection of light rays and the gravitational frequency shift. Once this issue is elucidated, it will be necessary to find laws governing this inertial–gravitational field,

[8] The analysis of data obtained in Sobral and Principe was published in 1920 by Dyson, Eddington, and Davidson.

having as a guide Newton's law of universal gravitation. We are going to see an argument showing that the gravitational frequency shift demands a new revision of our assumptions about the nature of space-time. Concretely, the Euclidean geometry ascribed to space, or the pseudo-Euclidean geometry of Minkowski space-time, will not be suitable to explain the gravitational frequency shift required by the Principle of equivalence. This will force us to admit that space-time geometry is not a priori determined, but the inertial–gravitational field is precisely the manifestation of the geometric properties of space-time, which should be determined by the matter distribution in order to observe Mach's Principle.

According to the Principle of equivalence, the frequency of a light ray rising a gravitational potential results to be redshifted. Let us consider a system source–sensor in a *non-accelerated* laboratory in the presence of a static (independent of time) uniform gravitational field. Whatever the gravitational influence on the pulses covering the distance between source and sensor could be, it is clear that all successive pulses will be affected in the same way, since the field does not change in time and all the pulses perform the same trajectory. Therefore the traveling time of the first pulse will be identical to the traveling time of the second one. However, if the successive pulses cover the distance between source and sensor in the same time, then they will arrive to the sensor with a time difference identical to the one of emission. In other words, the observed period T_{obs} would be equal to the emission period T_{src} and there would not be gravitational frequency shift at all!

In the context of Special Relativity T_{src} and T_{obs} are proper times measured on the world lines of the source and the sensor respectively. In the frame fixed to the laboratory—the source and sensor proper frame—the spatial Cartesian coordinates of source and sensor are constant along their world lines. Then the relation between proper time $\Delta\tau$ and laboratory coordinate time Δt is

$$\Delta\tau = c^{-1}\,\Delta s = c^{-1}\sqrt{g_{ij}\,\Delta x^i\,\Delta x^j} = \sqrt{g_{00}}\,\Delta t$$

Obviously, in Special Relativity it is $g_{00} = 1$; therefore the proper time is coincident with the coordinate time measured in the proper frame. Since the coordinate times involved in the examined experiment are equal at the emission and the reception, then the gravitational frequency shift will force to consider a theory where the relation between proper time (the clock rate) and coordinate time result to be altered by the presence of a gravitational potential. In fact, the only difference between a clock placed next to the sensor and another clock placed next to the source is the different positions each one occupies in the gravitational potential (remarkably, the gravitational forces acting on both clocks are equal, because we assumed a uniform gravitational field). The former equation then suggests that g_{00} should contain information about the gravitational potential. In a stationary gravitational field, g_{00} should be a function of the position such that the expression

$$\frac{\nu_{\text{obs}}}{\nu_{\text{src}}} = \frac{T_{\text{src}}}{T_{\text{obs}}} = \frac{\sqrt{g_{00}(\mathbf{r}_{\text{src}})}}{\sqrt{g_{00}(\mathbf{r}_{\text{obs}})}}\,\frac{\Delta t_{\text{emission}}}{\Delta t_{\text{reception}}} = \sqrt{\frac{g_{00}(\mathbf{r}_{\text{src}})}{g_{00}(\mathbf{r}_{\text{obs}})}} \tag{8.7}$$

reflects the result (8.6) coming from the Principle of equivalence. But result (8.6) is valid only if $|\Delta\Phi/c^2| << 1$. In the approximation of "weak" gravitational potential i.e., $|\Phi/c^2| << 1$—the result (8.6) and Eq. 8.7) are coincident at the lowest order if

$$g_{00} \approx 1 + \frac{2\,\Phi}{c^2} \qquad \frac{|\Phi|}{c^2} << 1 \tag{8.8}$$

Thus the gravitational potential would become a feature of metric tensor. But the metric tensor is a unique geometric object: its components intermingle under changes of reference system. Then, if we accept that the gravitational potential in a reference system is associated with g_{00}, we shall have to accept in general that the complete metric tensor—not only one of its components—contains the information about the inertial–gravitational field. In such a case the space-time geometry no longer will be an a priori given structure: it will become an attribute determined by the matter distribution in the universe, so accomplishing Mach's Principle. The space-time no longer will be pseudo-Euclidean, as it was so far assumed, because its geometry will become another dynamical variable. The properties commonly attributed to space, like isotropy and homogeneity, no longer will be taken as a truth, since they will be subjected to the dictates of the matter inside it. Before General Relativity the space-time was the stage where the physical phenomena took place. The stage influenced on the phenomena, because it was the only cause of the inertial properties of bodies; but it did not receive in return any influence, since its geometric properties were immutable. From General Relativity the space-time geometry no longer is the immutable stage but it is just another participant of physical phenomena described by Dynamics. The geometry influences on matter but, at the same time, it is determined by the matter distribution in the universe.

> *...it is contrary to the mode of thinking in science to conceive of a thing (the space-time continuum) which acts itself, but which cannot be acted upon. This is the reason why E. Mach was led to make the attempt to eliminate space as an active cause in the system of mechanics.*
>
> A. Einstein, 1922

In this way the Principle of equivalence together with Mach's Principle lead to the necessity of reviewing once again our notions of space and time, abandoning the pseudo-Euclidean geometry of Minkowski space-time in favor of a more general geometry able to incorporate the inertial–gravitational phenomena. In General Relativity theory the space-time geometry is not a priori fixed, but it is governed by laws determining it as a function of the matter distribution. The rest of the laws of Physics, like the Principle of inertia and the laws of electromagnetism, will be reformulated in this new geometrical context. Naturally, there is a non-relativistic limit where the theory meets again the Newtonian laws for the particle movement in a gravitational field, and for the gravitational potential as a function of its sources. In order to establish the link with the old theory, we shall bear in mind the relation (8.8) between gravitational potential and metric tensor.

8.4. RIEMANNIAN GEOMETRY

General Relativity postulates that space-time is provided with a *pseudo-Riemannian* geometry determined by the energy and momentum belonging to the matter and the radiation in the universe. The metric tensor plays the role of inertial–gravitational potential.

In a *Riemannian geometry* the distance ds between two infinitesimally separated points, whose coordinates are x^i and $x^i + \mathrm{d}x^i$ respectively, is a quadratic form of the coordinate differences[9]

$$\mathrm{d}s^2 = g_{ij}(x)\,\mathrm{d}x^i\,\mathrm{d}x^j \tag{8.9}$$

The classical physics' Euclidean space and the Special Relativity's pseudo-Euclidean space-time are particular cases of Riemannian geometries, which are characterized by having privileged coordinates—Cartesian coordinates—that make possible to write ds in a same and simple way at all the space points (the components of metric tensor have the same values in the whole space). The existence of Cartesian coordinates in these spaces so far concentrated our interest in those transformations linking different Cartesian systems (rotations, Lorentz boosts, and their combinations). However, in an arbitrary geometry there is not such kind of special coordinates. Therefore the transformations of interest have to be extended to all possible coordinate changes. Now, if the quadratic form $\mathrm{d}s^2$ defines a geometrical property of space, then its value will have to be independent of the used coordinates. In order to satisfy this requirement the metric tensor components must transform in a proper way under a *general coordinate change*. Let $x^{i'} = x^{i'}(x^i)$ be an arbitrary coordinate change, then it is $\mathrm{d}x^i = (\partial x^i/\partial x^{i'})\mathrm{d}x^{i'}$ and it results

$$\mathrm{d}s^2 = g_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j = g_{ij}\,\frac{\partial x^i}{\partial x^{i'}}\,\frac{\partial x^j}{\partial x^{j'}}\,\mathrm{d}x^{i'}\,\mathrm{d}x^{j'}$$

In order that ds be invariant, the metric tensor components in the new coordinate system must be

$$g_{i'j'} = g_{ij}\,\frac{\partial x^i}{\partial x^{i'}}\,\frac{\partial x^j}{\partial x^{j'}} \tag{8.10}$$

which means that the coefficients for the transformation of tensor components under a general coordinate change are the functions

$$\Lambda^j{}_{j'} = \frac{\partial x^j}{\partial x^{j'}} \tag{8.11}$$

[9] We use to say "pseudo-Riemannian" when alluding to spaces like the space-time where the metric does not have a definite signature but one of its eigenvalues has opposite sign. In a pseudo-Riemannian geometry there is a causal structure of "light cones," analogous to that of Minkowski space-time, and ds is not a distance but the interval between close events.

In particular, the transformation of the components of a contravariant vector

$$V^{j'} = \frac{\partial x^{j'}}{\partial x^j} V^j \tag{8.12}$$

proves that the coordinates x^j of an event do not transform as four-vector components under a general coordinate change (the four-vector character of x^j is only recovered if the coordinate change is restricted to be linear and homogeneous). The object that does retain its condition of being a contravariant four-vector is the four-vector tangent to a curve (the four-velocity, in the case of a particle world line). In fact, if $x^i = x^i(\tau)$ are parametric equations for a curve, where τ is a parameter identifying each point on the curve, then the components of the vector tangent to the curve are $V^i = \mathrm{d}x^i(\tau)/\mathrm{d}\tau$; therefore, under a general coordinate change (which does not affect the parameter, since this must be regarded as a property of the curve), the vector components will transform according to [10]

$$V^{i'} = \frac{\mathrm{d}x^{i'}}{\mathrm{d}\tau} = \frac{\partial x^{i'}}{\partial x^i}\frac{\mathrm{d}x^i}{\mathrm{d}\tau} = \frac{\partial x^{i'}}{\partial x^i} V^i$$

The derivatives $\partial_i O$ of an invariant function O behave as components of a covariant vector:

$$\partial_{i'} O = \frac{\partial x^i}{\partial x^{i'}} \partial_i O = \Lambda^i{}_{i'}\, \partial_i O \tag{8.13}$$

Instead, the partial derivatives of the components of a contravariant vector do not behave as tensor components under general coordinate changes:

$$\begin{aligned}\partial_{k'} V^{i'} &= \partial_{k'}\left(\frac{\partial x^{i'}}{\partial x^i} V^i\right) = \frac{\partial x^k}{\partial x^{k'}}\partial_k\left(\frac{\partial x^{i'}}{\partial x^i} V^i\right)\\ &= \frac{\partial x^k}{\partial x^{k'}}\frac{\partial x^{i'}}{\partial x^i}\partial_k V^i + V^i \frac{\partial x^k}{\partial x^{k'}}\frac{\partial^2 x^{i'}}{\partial x^k \partial x^i}\end{aligned}$$

The last term, which vanishes only if the coordinate change is linear (as it happens, for instance, with Lorentz group transformations in Minkowski space-time), prevents that $\partial_j V^i$ can be regarded as tensor components. For a later application, we shall rewrite this last term in a different way; let us differentiate the identity $\delta^{i'}_{k'} = \partial x^{i'}/\partial x^{k'}$:

$$\delta^{i'}_{k'} = \frac{\partial x^k}{\partial x^{k'}}\frac{\partial x^{i'}}{\partial x^k} \qquad \Rightarrow \qquad 0 = \frac{\partial x^k}{\partial x^{k'}}\frac{\partial^2 x^{i'}}{\partial x^k \partial x^i} + \frac{\partial x^{i'}}{\partial x^i}\frac{\partial^2 x^k}{\partial x^{j'}\partial x^{k'}}\frac{\partial x^{j'}}{\partial x^k}$$

By exchanging dummy indexes it is then obtained

$$\partial_{k'} V^{i'} = \frac{\partial x^{i'}}{\partial x^i}\left(\frac{\partial x^k}{\partial x^{k'}}\partial_k V^i - V^j \frac{\partial x^{j'}}{\partial x^j}\frac{\partial^2 x^i}{\partial x^{j'}\partial x^{k'}}\right) \tag{8.14}$$

[10] The definitions of vectors and covectors in *differential geometry* are sketched in Complement 8A.

Complement 8A: *Vectors and covectors*

Usually a vector V is represented by means of an arrow characterized by its modulus and the angles it forms with the Cartesian axes. V can be decomposed in an orthonormal basis $\{\mathbf{e}_i\}$ as $V = V^i\,\mathbf{e}_i$. Components V^i change under rotations of the orthonormal basis, but the vector itself does not change: it is a geometric object. The notions of modulus, angle, and orthonormality come from the space metric structure, and the idea of "Cartesian axes" supposes that the metric structure is Euclidean. However, vectors can also be defined in spaces that are not provided with metric structure at all. With this aim, let us consider a curve in a space provided with a coordinate system only, whose parametric equations are $x^i = x^i(\lambda)$. The operator $\mathrm{d}/\mathrm{d}\lambda$ differentiating functions along the curve with respect to the parameter λ is

$$\frac{\mathrm{d}}{\mathrm{d}\lambda} = \frac{\mathrm{d}x^i(\lambda)}{\mathrm{d}\lambda}\,\partial_i \tag{8A.1}$$

Thus the derivative at a point P along each curve going through P is a linear combination of partial derivatives. Inversely, for each linear combination of partial derivatives $V = V^i\,\partial_i$ there is a curve going through P such that $V^i = \mathrm{d}x^i(\lambda)/\mathrm{d}\lambda|_{\mathrm{P}}$. This means that the set of derivatives along curves going through P is a vector space, since it is closed under vector addition and multiplication by real numbers; the operators $V = \mathrm{d}/\mathrm{d}\lambda|_{\mathrm{P}} = V^i\,\partial_i$ are the *vectors* and $\{\partial_i\}$ is a *coordinate basis*. The form of the components of $\mathrm{d}/\mathrm{d}\lambda$ in (8A.1) justifies calling this vector space *tangent space* $\mathbf{T}_{\mathrm{P}}$. The purely geometric character of $\mathbf{T}_{\mathrm{P}}$ definition is reflected in transformation (8.12), which shows that $V \in \mathbf{T}_{\mathrm{P}}$ does not depend on the used coordinates: $V^{i'}\,\partial_{i'} = V^i\,\partial_i$. At each point P there is a tangent space; a vector *field* is introduced by choosing a vector at each point.

Covectors or 1-*forms* are linear functionals on the space of vectors, i.e., they are applications $\tilde{\omega}$ such that $\tilde{\omega}(V)$ is a real number independent of the coordinate system. The linearity means that $\tilde{\omega}(aV + bU) = a\tilde{\omega}(V) + b\tilde{\omega}(U)$, where a, b are reals, V, $U \in \mathbf{T}_{\mathrm{P}}$. Linear combinations of 1-forms are defined as

$$(a\,\tilde{\omega} + b\,\tilde{\eta})(V) \equiv a\,\tilde{\omega}(V) + b\,\tilde{\eta}(V) \tag{8A.2}$$

so achieving that the 1-forms set has properties of a vector space at P, which is called *cotangent space* $\mathbf{T}_{\mathrm{P}}^*$. Using the linearity of 1-forms it results

$$\tilde{\omega}(V) = \tilde{\omega}(V^i\,\partial_i) = V^i\,\tilde{\omega}\,(\partial_i) \equiv V^i\,\omega_i \tag{8A.3}$$

The quantities ω_i transform like the components of a covariant vector: $\omega_{i'} = \tilde{\omega}\,(\partial_{i'}) = \tilde{\omega}\,[(\partial x^i/\partial x^{i'})\,\partial_i] = (\partial x^i/\partial x^{i'})\,\tilde{\omega}\,(\partial_i) = (\partial x^i/\partial x^{i'})\,\omega_i$. In order that the quantities ω_i can be regarded as the components of the 1-form $\tilde{\omega}$, a *dual coordinate basis* $\{\tilde{d}x^i\}$ in the cotangent space $\mathbf{T}_{\mathrm{P}}^*$ must be defined. In fact, if the 1-form $\tilde{d}x^i$ is defined as:

$$\tilde{\mathrm{d}}x^i\,(\partial_j) \equiv \delta^i_j \quad \text{then} \quad \tilde{\omega}\,(\partial_i) = \omega_i \Leftrightarrow \tilde{\omega} = \omega_i\,\tilde{\mathrm{d}}x^i \tag{8A.4}$$

An invariant function O defines the 1-form $\tilde{\mathrm{d}}O = \partial_i\,O|_{\mathrm{P}}\;\tilde{\mathrm{d}}x^i$ (see Eq. (8.13)), whose application to $V \in \mathbf{T}_{\mathrm{P}}$ is $\tilde{\mathrm{d}}O(V) = V^i\,\partial_i\,O|_{\mathrm{P}} = V(O)$ (V acting on O).

In the absence of a metric tensor, the operation of "rising and lowering indexes"—which would establish a relation between vectors and covectors—does not exist. Vectors and covectors are then genuinely different geometric objects.

The derivatives of the components of a covariant vector do not transform as tensor components either:

$$\partial_{k'} C_{i'} = \partial_{k'} \left(\frac{\partial x^i}{\partial x^{i'}} C_i \right) = \frac{\partial x^k}{\partial x^{k'}} \frac{\partial x^i}{\partial x^{i'}} \partial_k C_i + C_i \frac{\partial^2 x^i}{\partial x^{k'} \partial x^{i'}} \tag{8.5}$$

In this case, the term hindering the tensor character—the last one in Eqs. (8.5)—results to be symmetric. Therefore the antisymmetrized partial derivative $\partial_k C_i - \partial_i C_k$ does have tensor character. This property is also true for the antisymmetrized partial derivative of any completely antisymmetric covariant tensor.[11]

8.5. MOTION OF A FREELY GRAVITATING PARTICLE

In this section we shall reformulate the Principle of inertia in the context of a pseudo-Riemannian geometry. As we know, the motion of a freely gravitating particle (exclusively subjected to the inertial–gravitational field) does not depend on the particle properties, as a consequence of the equality between inertial and gravitational masses. This singular quality offers the possibility of *geometrizing* this kind of motion: instead of explaining it by means of a force field, we can describe it as the *natural* motion in a suitable geometry. Since the role of the inertial–gravitational field was assigned to the metric tensor, then a freely gravitating particle has to be considered as genuinely free of forces; therefore it must *inertially* move along those curves that the geometry characterizes as *natural*.

As commonly formulated in classical physics or Special Relativity, the Principle of inertia turns to the natural curves of Euclidean *plane* geometry, i.e. the straight lines. In Euclidean geometry the straight lines are remarkable curves because they have the property of making minimum the length between two given points. Analogously, in Minkowski pseudo-Euclidean geometry the rectilinear timelike world line—the inertial trajectory of a particle—has the property of making maximum the proper time along the curve joining a given pair of causally connected events (this property was shown in §4.5). Both the length in the first case and the proper time in the second one are related to the integral $\int \mathrm{d}s$ along the curve.[12] In general, the curve between a pair of given points making stationary (maximum or minimum) the value of the integral $\int \mathrm{d}s$ is called *geodesic*. The notion of geodesic is equally defined in a Riemannian geometry, since what characterizes such a geometry is the existence of a notion of distance or interval. *geodesic*

[11] This property makes possible to define the differential and integral calculus for completely antisymmetric covariant tensors without resorting to a metric or any other structure except for a well-behaved coordinate system. The completely antisymmetric covariant p-index tensors ($p \leq n$, n is the space dimension) are called *p-forms*.

[12] In General Relativity, like in Special Relativity, the integral $\int c^{-1} \mathrm{d}s$ along a timelike curve is identified with the reading of a clock traveling the curve (see §4.4 and 4.5).

Therefore, it is natural that the reformulation of the Principle of inertia turns to the notion of geodesic. To form an idea of the properties of geodesics in a Riemannian geometry, we shall appeal to the Riemannian geometry of a surface embedded in an Euclidean space (in this case the notion of distance on the surface is the one induced by the Euclidean space where the surface is embedded). Figure 8.5 uses as example the spherical surface embedded in a three-dimensional flat space. The sphere geodesics are the great circles. Figure 8.5 shows that two initially "parallel" geodesics (with a notion of parallelism taken from the exterior Euclidean space)—two meridians in this figure—do not remain parallel (in this example the meridians are parallel at the equator but they intersect at the poles). This *geodesic deviation* is proper of the *curved* spaces (as opposed to *flat* space of Euclidean geometry); this is precisely the Riemannian geometry property that is needed to express the relative acceleration between freely gravitating particles in non-uniform gravitational fields, as it was seen in §8.2 (see Figures 8.1 and 8.2). The separation between the initially parallel orbits in Figure 8.1 will be then described as a geodesic deviation in a curved space.

In General Relativity theory the Principle of inertia is stated:

Principle of inertia in a Riemannian geometry

A free particle moves along timelike geodesics ($ds^2 > 0$) *of space-time.*
A light ray propagates along null geodesics ($ds^2 = 0$) *of space-time.*

This entirely natural statement about freely gravitating motions should however pass a primary test: under non-relativistic conditions the classical law for the particle movement in a gravitational field must be recovered. The Principle of equivalence helped to establish a link between the Newtonian gravitational potential and the metric tensor component g_{00} (Eq. (8.8)), which resulted from demanding the gravitational frequency shift. The same relation (8.8) should also explain the particle movements in gravitational fields, in the "weak" potential approximation $|\Phi| << c^2$. To check the fulfillment of this requirement, let us remark that the property defining the geodesics—i.e., the one of making stationary the integral $\int ds$—identifies $\int ds$ with the *action functional* for the

Figure 8.5. Geodesic deviation in a curved surface immersed in a flat space.

freely gravitating particle (see Appendix). In order to provide this quantity with units of action, we shall multiply by mc.[13]

$$S = -mc \int \mathrm{d}s \tag{8.16}$$

The Newtonian movement for a freely gravitating particle should result from this action in the limit of a non-relativistic motion in a "weak" gravitational potential, i.e., when the particle moves at low velocity in a space-time whose geometry is similar to Minkowski space-time geometry. Concretely, the geometry must be such that a coordinate system should exist—at least in some region—where the metric tensor components do not differ much from Minkowskian values of Eq. (7.28) (in particular, $g_{00} \approx 1 + 2\Phi\, c^{-2}$, $|\Phi| << c^2$, and $g_{0\mu} = 0$, $\mu = 1, 2, 3$).[14] The particle movement will be non-relativistic if, in this coordinate system, it is satisfied that $|\mathrm{d}x^\mu| << \mathrm{d}x^0$. Thus the integrand in the action can be approximated as

$$\begin{aligned} -mc\,\mathrm{d}s &= -mc\sqrt{g_{ij}\mathrm{d}x^i\,\mathrm{d}x^j} \approx -mc\sqrt{(1+2\Phi c^{-2})\mathrm{d}x^{0^2} - \delta_{\mu\nu}\,\mathrm{d}x^\mu\,\mathrm{d}x^\nu} \\ &= -mc^2\,\mathrm{d}t\left[1 + 2\Phi c^{-2} - c^{-2}\delta_{\mu\nu}\frac{\mathrm{d}x^\mu}{\mathrm{d}t}\frac{\mathrm{d}x^\nu}{\mathrm{d}t}\right]^{1/2} \cong -mc^2\,\mathrm{d}t\left[1 + \frac{\Phi}{c^2} - \frac{1}{2}\frac{u^2}{c^2}\right] \\ &= \mathrm{d}t(-mc^2 - m\Phi + \frac{1}{2}mu^2) \end{aligned}$$

In this result we can recognize the classical Lagrangian for a particle in a gravitational field (see Appendix), besides the rest energy term which does not take part in the minimization of the action. Therefore, the geodesics of a quasi-Minkowskian geometry, which satisfies the condition (8.8), accurately describe the non-relativistic limit of a particle movement in a gravitational field.

In Special Relativity the inertial world line satisfies the second order differential equations $\mathrm{d}^2x^i/\mathrm{d}\tau^2 = 0$ (i.e., the four-velocity is constant: $\mathrm{d}U^i/\mathrm{d}\tau = 0$). In a Riemannian geometry the geodesic equation can be obtained through a calculus of variations from the action functional (8.16). As known, the curve making stationary a functional like the action (8.16) is that fulfilling the Euler-Lagrange equations (see Appendix). Let us consider any timelike curve joining the initial and final events that play the role of integration limits in the action. If λ is the curve parameter, then $\mathrm{d}s = [g_{ij}\mathrm{d}x^i\mathrm{d}x^j]^{1/2} = [g_{ij}(\mathrm{d}x^i/\mathrm{d}\lambda)(\mathrm{d}x^j/\mathrm{d}\lambda)]^{1/2}\mathrm{d}\lambda$. Thus the Lagrangian for a freely gravitating relativistic particle is

$$L = -mc\sqrt{g_{ij}\frac{\mathrm{d}x^i}{\mathrm{d}\lambda}\frac{\mathrm{d}x^j}{\mathrm{d}\lambda}} \tag{8.17}$$

[13] The minus sign implies that the stationary value of S is a minimum instead of a maximum.

[14] The condition $g_{0\mu} = 0$ is always eligible in a region, because it only means that the $x^\mu = constant$ lines are orthogonal to the hypersurfaces $x^0 = constant$.

The Euler-Lagrange equations coming from this Lagrangian result to be

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}\left(\frac{g_{ij}}{\sqrt{g_{ef}\dfrac{\mathrm{d}x^e}{\mathrm{d}\lambda}\dfrac{\mathrm{d}x^f}{\mathrm{d}\lambda}}}\frac{\mathrm{d}x^j}{\mathrm{d}\lambda}\right)-\frac{1}{2\sqrt{g_{ef}\dfrac{\mathrm{d}x^e}{\mathrm{d}\lambda}\dfrac{\mathrm{d}x^f}{\mathrm{d}\lambda}}}\frac{\partial g_{jk}}{\partial x^i}\frac{\mathrm{d}x^j}{\mathrm{d}\lambda}\frac{\mathrm{d}x^k}{\mathrm{d}\lambda}=0$$

These equations become simpler by using as parameter the interval $\mathrm{d}s$ (or the proper time $\mathrm{d}\tau = c^{-1}\mathrm{d}s$). In fact, in such a case the square root becomes a constant:

$$\frac{\mathrm{d}}{\mathrm{d}\tau}\left(g_{ij}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\right)-\frac{1}{2}\frac{\partial g_{jk}}{\partial x^i}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}=0 \tag{8.18}$$

particle energy–momentum conservation

When written in this way, the motion equations for a freely gravitating particle state that $p_i = mg_{ij}\mathrm{d}x^j/\mathrm{d}\tau$ will be conserved during the motion if the metric tensor components do not depend on the coordinate x^i.

In Eq. (8.18) $\mathrm{d}/\mathrm{d}\tau$ indicates the derivative along the particle world line; then it is valid that $\mathrm{d}g_{ij}/\mathrm{d}\tau = (\partial g_{ij}/\partial x^k)\mathrm{d}x^k/\mathrm{d}\tau$. Therefore

$$g_{ij}\frac{\mathrm{d}^2x^j}{\mathrm{d}\tau^2}+\left(\frac{\partial g_{ij}}{\partial x^k}-\frac{1}{2}\frac{\partial g_{jk}}{\partial x^i}\right)\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}=0$$

Finally, by recognizing that only the symmetric part of the parenthesis takes part in the contraction with the symmetric tensor $\mathrm{d}x^j/\mathrm{d}\tau\,\mathrm{d}x^k/\mathrm{d}\tau$, and using the inverse metric tensor g^{ij}, it is obtained

equations for a freely gravitating motion

$$\frac{\mathrm{d}^2x^i}{\mathrm{d}\tau^2}+\frac{1}{2}g^{il}\left(\frac{\partial g_{lk}}{\partial x^j}+\frac{\partial g_{lj}}{\partial x^k}-\frac{\partial g_{jk}}{\partial x^l}\right)\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}=0 \tag{8.19}$$

The functions

$$\Gamma^i_{jk}=\frac{1}{2}g^{il}\left(\frac{\partial g_{lk}}{\partial x^j}+\frac{\partial g_{lj}}{\partial x^k}-\frac{\partial g_{jk}}{\partial x^l}\right) \tag{8.20}$$

are called *Christoffel symbols*.

According to the Principle of equivalence, there are locally inertial frames at each event where the inertial–gravitational field vanishes and the laws of Physics become the ones we know in Special Relativity. As seen in Eq. (8.19), a locally inertial frame at a given event is that associated with coordinates such that Christoffel symbols vanish at the event. In fact, if Christoffel symbols are null then Eq. (8.19) will acquire the form of the Principle of inertia in Special Relativity. On the contrary, the use of different coordinates will introduce inertial–gravitational terms in the description of the freely gravitating motion (inertial or gravitational forces): Christoffel symbols are the geometrization of inertial–gravitational forces per unit of mass.[15]

[15] Christoffel symbols did not appear in the Special Relativity pseudo-Euclidean space-time just because they are null—not only at an event but everywhere—when Cartesian coordinates are used (the Cartesian components of the metric tensor are constant). However, they would appear if other coordinates were used.

The existence of coordinates such that the Christoffel symbols locally vanish is the signal that these symbols cannot be components of a tensor (if a tensor is null in a coordinate system then it will be null in any other coordinate system). This fact by no means invalidates that the geodesic described by Eq. (8.19) is a geometric object (independent of the coordinate system), since the tensor character has to be exhibited not by each separated term but by the entire equation. There is no doubt that the results of the calculus of variations from an invariant action like Eq. (8.16) must have a manifest tensor character. However, as it was mentioned in §8.4, the ordinary derivatives of vector components do not tensorially transform (see Eq. (8.14)). Therefore, the first term in Eq. (8.19)—$\mathrm{d}^2x^i/\mathrm{d}\tau^2 = \mathrm{d}U^i/\mathrm{d}\tau$—which would be the particle four-acceleration in Cartesian coordinates of Minkowski space-time, is not by itself a vector under general coordinate changes. Christoffel symbols in Eq. (8.19) then compensates the improper first term behavior for rendering the ensemble a four-vector; we shall call this ensemble four-acceleration:

$$a^i = \frac{\mathrm{d}U^i}{\mathrm{d}\tau} + \Gamma^i_{jk} U^j U^k \equiv \left(\frac{\mathrm{D}U}{\mathrm{D}\tau}\right)^i \tag{8.21}$$

Thus Eq. (8.19) says that the particle four-acceleration vanishes for a freely gravitating motion.

8.6. COVARIANT DERIVATIVE. MINIMAL COUPLING

Equation (8.21) shows the way of defining the *covariant derivative* of a vector along a curve $x^i = x^i(\tau)$, i.e., a derivative whose result is a vector. The covariant derivative of a field V^i along the curve whose tangent vector is $U^i = \mathrm{d}x^i/\mathrm{d}\tau$ is defined as

$$\begin{aligned}\left(\frac{\mathrm{D}V}{\mathrm{D}\tau}\right)^i &= \frac{\mathrm{d}V^i}{\mathrm{d}\tau} + \Gamma^i_{jk} U^j V^k \\ &= \frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\partial V^i}{\partial x^j} + \Gamma^i_{jk} U^j V^k = U^j(\partial_j V^i + \Gamma^i_{jk} V^k)\end{aligned} \tag{8.22}$$

According to Eq. (8.14), the tensor behavior of differentiation (8.22) will be guaranteed whenever the symbols Γ^i_{jk} transform as

$$\Gamma^{i'}_{j'k'} = \frac{\partial x^{i'}}{\partial x^i}\left(\frac{\partial x^j}{\partial x^{j'}}\frac{\partial x^k}{\partial x^{k'}}\Gamma^i_{jk} + \frac{\partial^2 x^i}{\partial x^{j'}\partial x^{k'}}\right) \tag{8.23}$$

Christoffel symbols (8.20) satisfy this transformation rule.

The covariant derivative (8.22) has the form of a directional derivative: it is the contraction between vector U^i, which gives the direction of differentiation, and a tensor describing the behavior of field V^i in the vicinity of the point at which the derivative is evaluated. Let us introduce the notation

$$V^i{}_{,j} \equiv \partial_j V^i \qquad\qquad V^i{}_{;j} \equiv V^i{}_{,j} + \Gamma^i_{jk} V^k \tag{8.24}$$

Complement 8B: *Derivative of a vector*

Here we shall use the geometric notion of vector that was defined in Complement 8A. The derivative of a vector $V = \mathrm{d}/\mathrm{d}\lambda = V^i \partial_i$ in the direction of another vector $U = \mathrm{d}/\mathrm{d}\mu = U^j \partial_j$ involves the differentiations of functions V^i and vectors ∂_i belonging to the coordinate basis:

$$\frac{\mathrm{D}V}{\mathrm{D}\mu} = \frac{\mathrm{D}}{\mathrm{D}\mu}(V^i \partial_i) = (U^j \partial_j V^i)\,\partial_i + V^k \frac{\mathrm{D}}{\mathrm{D}\mu}\partial_k \tag{8B.1}$$

Comparing Eqs. (8B.1) and (8.22) it results that the derivative of vector. ∂_k is

$$\frac{\mathrm{D}}{\mathrm{D}\mu}\partial_k = U^j\,\Gamma^i_{jk}\,\partial_i \tag{8B.2}$$

Differentiation in an Euclidean space. In an Euclidean space the derivatives of vectors belonging to the Cartesian basis are null (the Cartesian g_{ij} are constant and Christoffel symbols (8.20) vanish). The situation is different when curvilinear coordinates are used. As an example, let us consider polar coordinates in the plane: $x = r\cos\varphi$, $y = r\sin\varphi$. Then

$$\begin{aligned}\partial_r &= \frac{\partial x}{\partial r}\partial_x + \frac{\partial y}{\partial r}\partial_y = \cos\varphi\,\partial_x + \sin\varphi\,\partial_y\\ \partial_\varphi &= \frac{\partial x}{\partial \varphi}\partial_x + \frac{\partial y}{\partial \varphi}\partial_y = -r\sin\varphi\,\partial_x + r\cos\varphi\,\partial_y\end{aligned} \tag{8B.3}$$

Thus, for any vector $\mathrm{d}/\mathrm{d}\mu = U^r\partial_r + U^\varphi\partial_\varphi$ it is obtained

$$\frac{\mathrm{D}}{\mathrm{D}\mu}\partial_r = -U^\varphi \sin\varphi\,\partial_x + U^\varphi\cos\varphi\,\partial_y = U^\varphi\, r^{-1}\,\partial_\varphi$$

$$\frac{\mathrm{D}}{\mathrm{D}\mu}\partial_\varphi = U^r(-\sin\varphi\,\partial_x + \cos\varphi\,\partial_y) + U^\varphi(-r\cos\varphi\,\partial_x - r\sin\varphi\,\partial_y) = U^r\, r^{-1}\,\partial_\varphi - U^\varphi\, r\,\partial_r$$

and, according to (8B.2) , it results

$$\Gamma^\varphi_{\varphi r} = r^{-1} = \Gamma^\varphi_{r\varphi} \qquad \Gamma^r_{\varphi\varphi} = -r \qquad \text{(the rest of the symbols vanish)} \tag{8B.4}$$

which are the Christoffel symbols that would result from Eq. (8.20) by using the metric tensor polar components:[1]

$$\mathrm{d}s^2 = \mathrm{d}x^2 + \mathrm{d}y^2 = \mathrm{d}r^2 + r^2\,\mathrm{d}\varphi^2 \qquad \Rightarrow \qquad g_{rr} = 1,\quad g_{r\varphi} = 0,\quad g_{\varphi\varphi} = r^2 \tag{8B.5}$$

[1]Cartesian basis $\{\partial_x, \partial_y\}$ is orthonormal, since $g_{xx} = 1 = g_{yy}$, $g_{xy} = 0$. Instead, the polar coordinate basis (8B.3) is not; ∂_φ is not normalized, as it can be seen in (8B.5). On the other hand, the basis of polar versors, $\hat{\mathbf{e}}_r = \partial_r$, $\hat{\mathbf{e}}_\varphi = r^{-1}\partial_\varphi$, is orthonormal but it is not a coordinate basis like the ones used in this text. Those bases that cannot be written as partial derivatives in any coordinate system are called *non-holonomic*.

As was already mentioned, functions $V^i{}_{,j}$ do not constitute tensor components. Instead, functions $V^i{}_{;j}$ do transform as tensor components; we call this tensor *covariant derivative of* V^i (without relation to a curve at all). Using this notation, the covariant derivative of V^i along the curve $x^i = x^i(\tau)$ whose tangent vector is $U^i = \mathrm{d}x^i(\tau)/\mathrm{d}\tau$ is written as

$$\left(\frac{\mathrm{D}V}{\mathrm{D}\tau}\right)^i = U^j V^i{}_{;j} \tag{8.25}$$

The operation defined in Eq. (8.22) will have the whole features of a differentiation if Leibniz rule is fulfilled whenever the differentiated vector is written as the product of an invariant function and a vector: $V^i = O\,W^i$. For this, the covariant derivative of O is defined to be equal to the ordinary derivative of O (which is likewise invariant):

$$\frac{\mathrm{D}O}{\mathrm{D}\tau} = \frac{\mathrm{d}O}{\mathrm{d}\tau} = U^j \partial_j O = U^j O_{,j} \tag{8.26}$$

The covariant derivative can be defined for tensors of all types just by requiring the fulfillment of Leibniz rule under tensor product, and its commutativity with the index contraction operation. For instance, if the invariant O in Eq. (8.26) came from the contraction $C_i V^i$, then it would be

$$\frac{\mathrm{d}}{\mathrm{d}\tau}(C_i V^i) = \frac{\mathrm{D}}{\mathrm{D}\tau}(C_i V^i) = \left(\frac{\mathrm{D}C}{\mathrm{D}\tau}\right)_i V^i + C_i \left(\frac{\mathrm{D}V}{\mathrm{D}\tau}\right)^i \tag{8.27}$$

from where we can solve the covariant derivative of the covariant vector C_i:

$$\left(\frac{\mathrm{D}C}{\mathrm{D}\tau}\right)_i = U^j C_{i;j} \tag{8.28}$$

where

$$C_{i;j} \equiv C_{i,j} - \Gamma^k_{ji} C_k \tag{8.29}$$

In general, the covariant derivative of any kind of tensor is

$$\begin{aligned} T^{ij\ldots}{}_{ef\ldots;k} \equiv\ & T^{ij\ldots}{}_{ef\ldots,k} \\ & + \Gamma^i_{kl} T^{lj\ldots}{}_{ef\ldots} + \text{a term for each contravariant index} \\ & - \Gamma^l_{ke} T^{ij\ldots}{}_{lf\ldots} - \text{a term for each covariant index} \end{aligned} \tag{8.30}$$

Actually, a covariant derivative could be defined without resorting to the Christoffel symbols (8.20) associated with the metric tensor. Even if the space were not provided with a metric structure we only have to endow it with an *affine connection* $\Gamma^i{}_{jk}(x)$, verifying the transformation rule (8.23), to define a directional covariant derivative on it. In this case, the curve that verifies the

equation $\mathrm{D}U/\mathrm{D}\tau = 0\,(U^i = \mathrm{d}x^i/\mathrm{d}\tau)$ should not be called geodesic, since it would not be the result of becoming stationary the integral $\int \mathrm{d}s$ along the curve. Anyway this curve will have the property that its tangent vector U^i would remain "equal" to itself along the curve (this notion of "equal" would be defined by the affine connection itself). Such curve could be then called *autoparallel*. It can be said that any affine connection $\Gamma^i{}_{jk}$ defines a notion of *parallelism*: a vector V^i is parallel-transported along a curve if its covariant derivative in the direction of the vector U^i tangent to the curve vanishes. However, if the affine connection is linked to the metric structure as the *metric connection* defined by the Christoffel symbols (8.20) is, then the autoparallel curves will be coincident with geodesics, and the following important properties will result:

- Metric connection is symmetric [16].

$$\Gamma^i{}_{jk} = \Gamma^i{}_{kj} \tag{8.31}$$

  The connection symmetry guarantees the commutativity of two covariant derivatives of an invariant function

$$O_{;jk} = O_{;kj} \tag{8.32}$$

- The covariant derivatives of the metric tensor and its inverse are null

$$g_{ij;k} = 0 \qquad g^{ij}{}_{;k} = 0 \tag{8.33}$$

  This property makes possible that the operation of index raising and lowering commutes with the covariant derivative, since the metric tensor is "transparent" to the covariant derivative. Besides it establishes the validity of Leibniz rule for the scalar product of vectors $V \cdot W = g_{ij}\, V^i\, W^j$:

$$\frac{\mathrm{D}}{\mathrm{D}\tau}(V \cdot W) = \frac{\mathrm{D}V}{\mathrm{D}\tau} \cdot W + V \cdot \frac{\mathrm{D}W}{\mathrm{D}\tau} \tag{8.34}$$

  In particular, if U satisfies the geodesic equation, $\mathrm{D}\,U/\mathrm{D}\tau = 0$, then it will be $\mathrm{D}\,(U \cdot U)/\mathrm{D}\tau = 0$. This implies that the timelike, spacelike, or null character of a geodesic curve is conserved.
- Contracted Christoffel symbols result to be [17]

$$\Gamma^k_{jk} = \left(\ln\sqrt{|g|}\right)_{,j} \qquad \text{where} \quad g = \det(g_{ij}) \tag{8.35}$$

---

[16] Symmetry is lost when non-coordinate or *non-holonomic* bases are used (see Complements 8A and 8B), as a consequence of the lack of tensor character of Christoffel symbols. Non-symmetric connections (in coordinate bases) define a tensor called *torsion*: $T^i{}_{jk} = \Gamma^i{}_{jk} - \Gamma^i{}_{kj}$ (its tensor character is guaranteed by transformation (8.23)). $T^i{}_{jk}$ characterizes the non-commutativity of covariant derivatives of an invariant function: $O_{;jk} - O_{;kj} = T^i{}_{jk}\, O_{;i}$.

[17] Eq. (8.35) is obtained from an equality which is valid for the derivative of the determinant of any matrix: $\partial_k \ln|\det(M_{ij})| = M^{ij}\,\partial_k M_{ij}$, where M^{ij} is the inverse of M_{ij}.

As a consequence, the divergences of a vector V^i and an antisymmetric tensor F^{ij} are

$$V^i{}_{;i} = \frac{1}{\sqrt{|g|}}\left(\sqrt{|g|}V^i\right)_{,i} \qquad F^{ij}{}_{;i} = \frac{1}{\sqrt{|g|}}\left(\sqrt{|g|}F^{ij}\right)_{,i} \tag{8.36}$$

A locally inertial frame at an event O is a coordinate system $\{X^a\}$ such that $\Gamma^a{}_{bc}(x_O) = 0$ and $g_{ab}(x_O) = \mathrm{diag}(1, -1, -1, -1)$. According to Eq. (8.33), in a locally inertial frame at O it results $g_{ab,c}(x_O) = 0 = g^{ab}{}_{,c}(x_O)$. In order to construct such a frame, notice that the coordinate change

locally inertial frame

$$x^i \to x^i + \frac{1}{2}\Gamma^i{}_{jk}(x_O)(x^j - x_O{}^j)(x^k - x_O{}^k) + O[(x - x_O)^3]$$

cancels the $\Gamma^i{}_{jk}$'s at O (use the inverse transformation of Eq. (8.23) to prove it). The construction of coordinates $\{X^a\}$ is completed by performing a linear transformation, which keeps the $\Gamma^i{}_{jk}$'s null (see Eq. (8.23)), to leave the metric at O to the form diag $(1, -1, -1, -1)$. The locally inertial frames retain their character under Lorentz transformations. Complement 8C shows the construction of the locally inertial frame of *Riemann normal coordinates*.

If the metric tensor at an event O has the Minkowskian form in coordinates $\{X^a\}$, then the four-volume at the event O will adopt the Special Relativity usual form:

$$\text{four-volume} = \mathrm{d}X^0\,\mathrm{d}X^1\,\mathrm{d}X^2\,\mathrm{d}X^3$$

Therefore, in another coordinate system the four-volume is

$$\text{four-volume} = \frac{\partial(X^0, X^1, X^2, X^3)}{\partial(x^0, x^1, x^2, x^3)}\,\mathrm{d}x^0\,\mathrm{d}x^1\,\mathrm{d}x^2\,\mathrm{d}x^3$$

where the first factor is the Jacobian $J = \det\left(\partial X^a/\partial x^i\right)$ for the coordinate change $\{X^a\} \leftrightarrow \{x^i\}$. Taking determinant in (8.10) and using that $\det\left(g_{ab}\right) = -1$:

$$g_{ij} = \frac{\partial X^a}{\partial x^i}\frac{\partial X^b}{\partial x^j}g_{ab} \qquad \Rightarrow \qquad |g| = \det\left(\frac{\partial X^a}{\partial x^i}\right)^2 \times 1$$

Thus $J = |g|^{1/2}$ ($J > 0$ if the coordinate change does not modify the volume orientation). Then,

$$\text{four-volume} = \sqrt{|g|}\,\mathrm{d}x^0\,\mathrm{d}x^1\,\mathrm{d}x^2\,\mathrm{d}x^3 \tag{8.37}$$

Complement 8C: *Riemann normal coordinates*

The figure shows the construction of Cartesian coordinates in a flat space by using concepts that can be transferred to a Riemannian geometry, with the aim of providing this last geometry with a *normal* coordinate system in which a symmetric connection became null at a point O. We must draw the autoparallel curves (in this case, straight lines) going through point O, which will play the role of coordinate origin. We choose an orthonormal basis of vectors $\{\mathbf{e}_m\}$ at O. Each autoparallel curve can be identified with its tangent unitary vector U at the origin O. This vector U is expanded in the basis $\{\mathbf{e}_m\}$ as $U = U^m \mathbf{e}_m$.

Thus, the Cartesian coordinates of point P can be written as

$$X^m = s\,U^m \tag{8C.1}$$

where s is the distance between origin O and point P (in fact, $U^1 = \cos\theta$, $U^2 = \sin\theta$).

The procedure of drawing the autoparallel curves going through a given point O, and choosing a vector orthonormal basis $\{\mathbf{e}_m\}$ at O, can be applied in any Riemannian geometry. Then, for each point P there exists the length $s = \int \mathrm{d}s$ (or, as appropriate, the proper time $s\,c^{-1}$) of the autoparallel curve joining O and P (this autoparallel curve is unique in a vicinity of the origin), and the components U^m of the respective unitary tangent vector at O. Equation (8C.1) then defines *Riemann normal coordinates* X^m with origin at O for each point P. Equation (8C.1) also says that the parametric equations for autoparallel curves going through O are linear in the parameter s when they are written for normal coordinates: $X^m(s) = s\,U^m$. So, the components of the tangent vector U result to be constant in the coordinate basis $\{\partial/\partial X^m\}$: $U^m(s) = \mathrm{d}X^m(s)/\mathrm{d}s = U^m$ (see Complement 8A). The autoparallel equation is $\mathrm{D}U/\mathrm{D}s = 0$, thus yielding

$$\Gamma^m_{np}\,(\mathrm{P})\;U^n\;U^p = 0 \tag{8C.2}$$

Equation (8C.2) is fulfilled at any point P belonging to the autoparallel curve associated with U, but this does not imply the vanishing of connection $\Gamma^m{}_{np}$ (P). In particular, Eq. (8C.2) is fulfilled at O. Since any direction for U can be chosen at O, the only way that Eq. (8C.2) can be satisfied at O is through the vanishing of the symmetric connection: $\Gamma^m{}_{np}(\mathrm{O}) = 0$.

Finally, since the components of U in the coordinate basis $\{\partial/\partial X^m\}$ are $\mathrm{d}X^m/\mathrm{d}s = U^m$, it is clear that coordinate basis $\{\partial/\partial X^m\}$ and orthonormal basis $\{\mathbf{e}_m\}$ are coincident at O. As it happens in flat space, the orthonormality of the coordinate basis provides the standard (pseudo) Euclidean form to the metric tensor components g_{mn} at O, what completes the proof that Riemann normal coordinate system is a locally inertial frame at O:

$$\Gamma^m_{np}(\mathrm{O}) = 0 \qquad g_{mn}(\mathrm{O}) = \pm\,\mathrm{diag}(\pm 1, 1, 1, 1) \tag{8C.3}$$

It can also be proved that Riemann tensor (8.42) in coordinate basis $\{\mathrm{d}X^m\}$ verifies that

$$g_{mn,pq}(\mathrm{O}) = -\frac{1}{3}\left[R_{mpnq}(\mathrm{O}) + R_{mqnp}(\mathrm{O})\right] \tag{8C.4}$$

In general it is $|g'|^{1/2} = |\det(\Lambda^l{}_{l'})|\,|g|^{1/2}$. Multiplying this relation and Eq. (7.59) it results that $|g|^{1/2}\,\varepsilon_{ijkl}$ transforms as a pseudotensor under general coordinate change (see Note 12 in Chapter 7). The addition of factor $|g|^{1/2}$ to the Levi-Civita symbol gives to expression (7.58) the status of n-volume in any coordinate system. The hypersurface element (7.61) must also include factor $|g|^{1/2}$ in order to covariantly transform under general coordinate change.

The covariant derivative is the proper tool to give the Principle of equivalence a mathematical content. As it was seen, the Principle of equivalence states that the laws of Physics in a Riemannian geometry are such that they reduce to the Special Relativity form in a locally inertial frame. In their covariant formulation, the laws of Physics in Special Relativity are built with tensor magnitudes under Lorentz group transformations and ordinary Cartesian derivatives. Correspondingly, geometric (independent of the coordinate system) objects, namely tensors under general coordinate changes and covariant derivatives, will be used in Riemannian geometry to represent physical magnitudes and write the laws governing them. The laws of Physics will then have tensor character under general coordinate changes (*general covariance*), then manifesting that their statements are independent of the used coordinate system. But at each event there exists a locally inertial frame where Christoffel symbols locally vanish, the covariant derivatives locally become ordinary derivatives, and the metric tensor components locally adopt the form diag $(1, -1, -1, -1)$. In order that these properties of the locally inertial frames can reduce the laws of Physics to the form they have in Special Relativity, the Principle of equivalence is implemented in the following way:

Principle of equivalence and minimal coupling

> *The physical laws in the covariant formulation of Special Relativity translate to a Riemannian geometry by substituting partial derivatives by covariant derivatives.*

This statement prescribes the way in which the inertial–gravitational field, through Christoffel symbols, couples to the remaining fields in Nature by entering in the laws governing them.[18] This type of coupling is called *minimal* because it rules out any other possible modification of physical laws, as the addition of terms including tensors associated with the curvature—like Riemann tensor and others that we shall see in the next section—that vanish in Minkowski space-time. The geodesic equation, which governs the freely gravitating motion according to the Principle of inertia, exemplifies the former statement. As a second example, let us apply the statement for writing the conservation of the energy–momentum tensor of an isolated system in a Riemannian geometry (see Eq. (7.64)):

$$T^{ik}{}_{;k} = 0 \tag{8.38}$$

[18] Since the covariant derivatives of vectors do not commute, while partial derivatives do commute, the prescription is ambiguous for laws containing second derivatives because it does not fix the ordering of the derivatives. Maxwell's laws do not suffer this problem because they can be written as *first* order differential equations for the field tensor F_{ij}.

8.7. RIEMANN TENSOR. EINSTEIN EQUATIONS

Newton's law of universal gravitation implies that the gravitational potential satisfies a second order differential equation:

$$\nabla^2 \Phi = 4\pi G \rho_m \tag{8.39}$$

where ρ_m is the mass density which plays the role of source for the gravitational field, and $G = 6.67 \times 10^{-11}\,\mathrm{m^3\,kg^{-1}\,s^{-2}}$ is the universal gravitation constant. Since the gravitational potential is a feature of the metric tensor, then the tensor laws governing the space-time geometry have to be differential equations in second derivatives of metric tensor. There is a tensor built with second derivatives of metric tensor which takes part in the study of geodesic deviation (the relative acceleration between close geodesics). The geodesic deviation, that characterizes the curved spaces, is the geometric correlate of tidal forces between freely gravitating particles in non-uniform gravitational fields. According to Eq. (8.5) tidal forces are second derivatives of the gravitational potential; their geometrization leads to a tensor depending on second derivatives of the metric (see Complement 8D). This tensor is the *Riemann tensor*[19]

$$R^i{}_{jkl} \equiv \Gamma^i{}_{lj,k} - \Gamma^i{}_{kj,l} + \Gamma^i_{ke}\,\Gamma^e_{lj} - \Gamma^i_{le}\,\Gamma^e_{kj} \tag{8.40}$$

Each affine connection $\Gamma^i{}_{jk}$ defines a Riemann tensor. In the case of the metric connection—which is given by the Christoffel symbols (8.20)—the Riemann tensor becomes a magnitude that depends on second and first derivatives of the metric. The quantities $R^i{}_{jkl}$ defined in Eq. (8.40) behave as tensor components because of the transformation (8.23) of elements $\Gamma^i{}_{jk}$. As a tensor associated with the affine connection, the Riemann tensor expresses the non-commutativity of covariant derivatives of a vector, whose direct consequence is that the vector parallel transport between two given points depends on the path chosen to join the points.[20] In Euclidean plane geometry there is neither geodesic deviation nor the parallel transport depends on the path; for this reason, we call *flat* any connection whose Riemann tensor vanishes.[21]

The Riemann tensor satisfies the *Bianchi identities*[22]

$$R^i{}_{jkl;e} + R^i{}_{jle;k} + R^i{}_{jek;l} = 0 \tag{8.41}$$

---

[19] Riemann tensor is antisymmetric in the last pair of indexes: $R^i{}_{lkj} = -R^i{}_{ljk}$.

[20] Riemann tensor characterizes the non-commutativity of the covariant derivatives of a vector: $V^i{}_{;jk} - V^i{}_{;kj} = T^l{}_{jk}\,V^i{}_{;l} + R^i{}_{lkj}\,V^l$.

[21] The element of arc for a cylinder of radius a is $\mathrm{d}\ell^2 = a^2\,\mathrm{d}\varphi^2 + \mathrm{d}z^2$, and its Riemann tensor is null. So the cylinder is an example of flat geometry. Except if they are regarded as surfaces embedded in a space of a larger dimension, the cylinder and the plane are *locally* indistinguishable, since they share the same geometry (by substituting the angle φ with the Cartesian coordinate $y = a\varphi$ it results $\mathrm{d}l^2 = \mathrm{d}y^2 + \mathrm{d}z^2$). The only differences between the cylinder and the plane are *global* (the cylinder has closed geodesics), and go outside the scope of the local description provided by Riemann tensor.

[22] Equation (8.41) is valid for any torsionless connection.

When Christoffel symbols (8.20) are used, the Riemann tensor takes the form

$$R_{ijkl} = \frac{1}{2}\left(g_{il,jk} + g_{jk,il} - g_{ik,jl} - g_{jl,ik}\right) + g_{ef}\left(\Gamma^{e}_{jk}\Gamma^{f}_{il} - \Gamma^{e}_{jl}\Gamma^{f}_{ik}\right) \tag{8.42}$$

where $R_{ijkl} = g_{ie} R^{e}{}_{jkl}$.

Ricci tensor is defined as

$$R_{jl} \equiv R^{k}{}_{jkl} \tag{8.43}$$

Ricci tensor for the symmetric connection (8.20) is symmetric and equal to [23]

$$R_{ij} = \frac{1}{\sqrt{|g|}}\left(\sqrt{|g|}\,\Gamma^{k}_{ij}\right)_{,k} - \left(\ln\sqrt{|g|}\right)_{,ij} - \Gamma^{k}_{li}\Gamma^{l}_{jk} \tag{8.44}$$

Finally, the *curvature scalar* is the invariant

$$R \equiv g^{ij} R_{ij} \tag{8.45}$$

In order to build equations governing the metric tensor, Einstein took into account that the mass density acting as a source in Eq. (8.39) is not by itself a magnitude with a defined geometric behavior. In Relativity the relativistic energy density, which replaces the mass density in the conservation laws, is merely one of the components of the energy–momentum tensor T^{ij}; therefore this tensor has to take the role of source in the equations governing the metric tensor. The other side of the equations should be built from the Ricci tensor, since it is a tensor of the same type than T^{ij} that contains second derivatives of the metric. After 2 years of diverse attempts, toward the end of 1915 Einstein proposed to equalize the energy-momentum tensor T^{ij} to a symmetric tensor which had, like T^{ij}, zero covariant divergence (1915b). Einstein equations express the relation between geometry and matter in the following way [24]

$$R_{ij} - \frac{1}{2} g_{ij} R = \frac{8\pi G}{c^4} T_{ij} \tag{8.46}$$

Einstein equations

[23] The torsionless connections satisfy $R^{i}{}_{lkj} + R^{i}{}_{kjl} + R^{i}{}_{jlk} = 0$. The metric connection besides fulfills $R_{ilkj} = R_{kjil}$, what provides the symmetry to Ricci tensor.

[24] *Einstein tensor* $G_{ij} \equiv R_{ij} - (1/2)\, g_{ij} R$ is the sole two index symmetric tensor built from first and second derivatives of the metric which results to be linear in the last ones, is divergenceless and vanishes in a flat geometry. In four or less dimensions this uniqueness is retained even if the requirement of linearity on the second derivatives is released (Lovelock, 1971). It can be proved that $g^{jk} G_{ij;k} \equiv 0$ by starting from Bianchi identities. For a direct calculation, use a locally inertial frame with origin at the point where the involved magnitudes are evaluated. Thus the expressions will become simpler as a consequence of the vanishing of Christoffel symbols and the first derivatives of the metric tensor at the coordinate origin. The result will be valid in any coordinate system, since the vanishing of a tensor does not depend on the used coordinates.

Complement 8D: *Geodesic deviation*

In §8.2 we studied the relative acceleration between two close freely falling movements, in the framework of Newtonian gravity. Equation (8.5) shows that the relative acceleration depends on second derivatives of the gravitational potential. In General Relativity the geometric correlate of this relative acceleration is the *geodesic deviation*. If $x^i(\tau)$ is a geodesic or autoparallel curve (in what follows the affine connection is not necessarily metric but it must be symmetric), a close curve $x^i(\tau)+\delta x^i(\tau)$ will be geodesic as well if the variation $\delta x^i(\tau)$ is such that

$$\delta\left[\frac{\mathrm{d}^2 x^i}{\mathrm{d}\tau^2}+\Gamma^i_{jk}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}\right]=0 \tag{8D.1}$$

In this way the geodesic equation, which is fulfilled by the first curve, will also be satisfied by the close curve under study. The former condition means that

$$\frac{\mathrm{d}^2\delta x^i}{\mathrm{d}\tau^2}+\Gamma^i_{kj,l}\,\delta x^l\frac{\mathrm{d}x^k}{\mathrm{d}\tau}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}+2\Gamma^i_{jk}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}\,\delta x^k}{\mathrm{d}\tau}=0 \tag{8D.2}$$

The displacement $\delta x^i(\tau)$ is a four-vector; its derivative along the geodesic is

$$\frac{\mathrm{D}\delta x^i}{\mathrm{D}\tau}=\frac{\mathrm{d}\delta x^i}{\mathrm{d}\tau}+\Gamma^i_{jl}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\,\delta x^l \tag{8D.3}$$

Differentiating Eq. (8D.3) along the geodesic one obtains

$$\frac{\mathrm{D}^2\delta x^i}{\mathrm{D}\tau^2}=\frac{\mathrm{d}}{\mathrm{d}\tau}\left[\frac{\mathrm{d}\delta x^i}{\mathrm{d}\tau}+\Gamma^i_{jl}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\,\delta x^l\right]+\Gamma^i_{kr}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}\left[\frac{\mathrm{d}\delta x^r}{\mathrm{d}\tau}+\Gamma^r_{jl}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\,\delta x^l\right]=$$

$$\frac{\mathrm{d}^2\delta x^i}{\mathrm{d}\tau^2}+\Gamma^i_{jl,k}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\,\delta x^l+\Gamma^i_{lr}\frac{\mathrm{d}^2x^r}{\mathrm{d}\tau^2}\,\delta x^l+2\Gamma^i_{jk}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}\delta x^k}{\mathrm{d}\tau}+\Gamma^i_{kr}\Gamma^r_{jl}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\,\delta x^l$$

The second derivative of $x^r(\tau)$ can be substituted by $-\Gamma^r{}_{kj}\,\mathrm{d}x^k/\mathrm{d}\tau\;\mathrm{d}x^j/\mathrm{d}\tau$, since $x^r(\tau)$ is a geodesic. Using the Eq. (8D.2) and applying the Riemann tensor definition (8.40), then the relative acceleration between close geodesics or geodesic deviation results to be

$$\frac{\mathrm{D}^2\delta x^i}{\mathrm{D}\tau^2}=R^i{}_{jkl}\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\frac{\mathrm{d}x^k}{\mathrm{d}\tau}\,\delta x^l \tag{8D.4}$$

As we are going to show now, constant $8\pi G c^{-4}$ is required for recovering the gravitation law (8.39) in the non-relativistic limit of weak field.

Einstein equations (8.46) can be written in a slightly different way: contracting indexes in Eq. (8.46), and noting that the trace $g^i{}_i=g^{ij}g_{ji}=\delta^i{}_i$ is equal to the space-time dimension $n=4$, it results

$$-R=8\pi G c^{-4}T \tag{8.47}$$

where $T = T^i{}_i$ is the trace of the energy–momentum tensor. Replacing the result in Eq. (8.46) it is obtained

$$R_{ij} = \frac{8\pi G}{c^4}(T_{ij} - \frac{1}{2} g_{ij} T) \tag{8.48}$$

linearization of Einstein equations

Einstein equations (8.46) are involved non-linear differential equations for the components of metric tensor. Nevertheless, they can be linearized if the field is "weak," acquiring a more familiar aspect. A weak field is a geometry allowing a coordinate system such that the metric tensor components are written as $g_{ij} = \eta_{ij} + h_{ij}$, where $\eta_{ij} = \mathrm{diag}\,(1, -1, -1, -1)$ and $|h_{ij}| << 1$. In Eq. (8.42) the products of Christoffel symbols are quadratic in derivatives of the h_{ij}'s; therefore they do not take part in an approximation that is linear in the h_{ij}'s. Then

$$R_{ij} = g^{kl} R_{kilj} \approx \frac{1}{2} \eta^{kl} (h_{kj,il} + h_{il,kj} - h_{kl,ij} - h_{ij,kl}) \tag{8.49}$$

The linearization of equations (8.46) should lead to Newton's law of universal gravitation for the potential Φ associated with h_{00} (according to Eq. (8.8), it is $h_{00} \approx 2\,\Phi\, c^{-2}$). Let us then consider the component 00 of the linearized Einstein equations, for an inertial–gravitational field independent of the time coordinate: $g_{ij,0} = 0$. According to Eq. (8.49), the linearized form of R_{00} is

$$R_{00} \approx -\frac{1}{2} \eta^{\mu\nu} h_{00,\nu\mu} = \frac{1}{2} \nabla^2 h_{00}$$

On the other hand, non-relativistic matter satisfies that $p_o << \rho_o$, $T \approx \rho \approx T_{00}$ (see §7.6, in particular Eqs. (7.72)-(7.74)). Here ρ is the relativistic energy density: $\rho \approx \rho_m c^2$. After replacing in Eq. (8.48) it results

$$\nabla^2 h_{00} \approx \frac{8\pi G}{c^2} \rho_m$$

which is precisely the law of universal gravitation with $h_{00} \approx 2\Phi\, c^{-2}$.

The linearized Riemann tensor is invariant under the transformation

$$h_{ij} \to h_{ij} - \xi_{i,j} - \xi_{j,i} \tag{8.50}$$

that resembles the gauge transformation (7.87) for the electromagnetic potential. This gauge invariance is then present in linearized Einstein equations. The quantities $|\xi_{i,j}|$ in Eq. (8.50) have to be much smaller than the unity in order to preserve the character of metric perturbation for h_{ij}. The gauge transformation (8.50) can be regarded as a first order result for the transformation (8.10) of metric tensor components under the infinitesimal coordinate change

$$x^i \to x^i + \eta^{ij} \xi_j(x^i) \qquad |\xi_{i,j}| << 1 \tag{8.51}$$

The gauge freedom for the perturbation h_{ij} can be exploited to choose those coordinate systems where the linearized equations have their simpler form. Thus, it is possible to choose the four functions ξ_j that force the h_{ij}'s to accomplish conditions similar to Lorentz gauge (7.88):

Lorentz gauge

$$\eta^{kl}\, h_{kj,l} = \frac{1}{2}\,\eta^{kl}\, h_{kl,j} \tag{8.52}$$

By replacing Eq. (8.52) in Eq. (8.49)

$$R_{ij} \approx -\frac{1}{2}\,\eta^{kl}\, h_{ij,kl} = -\frac{1}{2}\,\Box\, h_{ij} \tag{8.53}$$

The linearized Einstein equations (8.46) and the gauge condition (8.52) become clearer when written with the tensor

$$\bar{h}_{ij} \equiv h_{ij} - \frac{1}{2}\eta_{ij}\,\eta^{kl}\, h_{kl} \quad \text{or} \quad h_{ij} = \bar{h}_{ij} - \frac{1}{2}\eta_{ij}\,\eta^{kl}\,\bar{h}_{kl} \tag{8.54}$$

so yielding

$$\Box\,\bar{h}_{ij} \approx -\frac{16\pi G}{c^4}\,T_{ij} \qquad \eta^{kl}\,\bar{h}_{kj,l} = 0 \tag{8.55}$$

Newtonian limit

The Newtonian limit of the theory is reached when the only considered source for the gravitational field in Eq. (8.55) is a rest energy ρ independent of x^0. In such a case it is $T_{ij} \approx \mathrm{diag}\,(\rho, 0, 0, 0)$ and Eq. (8.55) are solved by $\bar{h}_{ij} = \mathrm{diag}\,(4\,\Phi\,c^{-2},\ 0,\ 0,\ 0)$, where Φ is the Newtonian potential. Therefore it is $h_{ij} \approx 2\,\Phi\,c^{-2}\ \mathrm{diag}\ (1,\ 1,\ 1,\ 1)$, so the metric corresponding to the Newtonian limit, in a coordinate system where the Lorentz gauge is satisfied, is

$$\mathrm{d}s^2 \approx \left(1 + \frac{2\Phi}{c^2}\right) c^2\,\mathrm{d}t^2 - \left(1 - \frac{2\Phi}{c^2}\right)(\mathrm{d}x^2 + \mathrm{d}y^2 + \mathrm{d}z^2) \tag{8.56}$$

Since this metric does not depend on x^0, the freely gravitating particles conserve p_0 (see Eq. (8.18)). If the particles are non-relativistic ($u << c$), then the proper time along their world lines can be approximated by $\mathrm{d}\tau^2 = c^{-2}\,\mathrm{d}s^2 \approx \mathrm{d}t^2\,(1 + 2\Phi\,c^{-2} - u^2\,c^{-2})$; so the conservation of $c\,p_0$ corresponds to the conservation of the classical mechanical energy: $c\,p_0 = mc^2\ g_{00}\ \mathrm{d}t/\mathrm{d}\,\tau \approx mc^2(1 + 2\Phi\,c^{-2})\,(1 + 2\Phi\,c^{-2} - u^2\,c^{-2})^{-1/2} \approx mc^2 + (1/2)\ m\ u^2 + m\,\Phi$.[25]

gravitational waves

According to Eq. (8.48) "vacuum" Einstein equations, i.e., the equations for vanishing energy–momentum tensor, are $R_{ij} = 0$. Equation (8.53) shows that the vacuum equations for h_{ij} are

$$\Box\, h_{ij} = 0 \tag{8.57}$$

[25] The Newtonian limit for the geodesic deviation (8D.4) between non-relativistic particles is $\mathrm{d}^2\delta x^\alpha/\mathrm{d}t^2 \approx R^\alpha{}_{00\beta}\,c^2\,\delta x^\beta \approx (1/2)\,\eta^{\alpha\gamma}\,h_{00,\gamma\beta}\,c^2\,\delta x^\beta \approx \eta^{\alpha\gamma}\,\Phi_{,\gamma\beta}\,\delta x^\beta$, in agreement with Eq. (8.5).

indicating that the perturbation h_{ij} is a *gravitational wave* which propagates at the speed of light in Minkowski space-time.[26] As an example we shall study a plane gravitational wave: $h_{ij} = H_{ij}\,\psi(k_k x^k)$. Equation (8.57) is fulfilled for any null wave four-vector k_k and any symmetric and constant H_{ij}. But it is still necessary to verify the Lorentz gauge (8.52), which is indispensable to the validity of Eq. (8.57):

$$H_{kj}\,k^k = \frac{1}{2}\,\eta^{kl}\,H_{kl}\,k_j \tag{8.58}$$

As it happens in electromagnetism (see §7.7), Lorentz gauge does not completely fix the gauge freedom of the theory, since there exist gauge transformations (8.50) that do not alter Lorentz gauge. In fact, once Lorentz gauge is chosen, the still remaining gauge transformations are those such that $\Box\xi_i = 0$.[27] In order to exemplify this residual gauge freedom, let us consider a monochromatic plane wave that propagates along the x direction: $k_j = (k, -k, 0, 0)$, $h_{ij} = H_{ij}\cos k(x - ct)$. As above mentioned, the gauge transformation generated by $\xi_i = \Xi_i\,k\,\sin k(x - ct)$ does not alter Lorentz gauge. This functional form of ξ_i is such that the resulting gauge transformation (8.50), for the wave h_{ij} under consideration, becomes mere algebraic relations among amplitudes Ξ_i and H_{ij}. This makes possible to use the four constants Ξ_i to cancel four components of H_{ij}. However, because ξ_i only depends on t, x, the transversal sector of H_{ij}, $(H_{22},\ H_{23},\ H_{33})$, is not affected by the gauge transformation generated by ξ_i, so it cannot be cancelled. Instead, wave components H_{i0} can be cancelled. In fact, the gauge transformation (8.50) for $j = 0$ becomes

$$H_{00} \to H_{00} + 2\,\Xi_0 \qquad H_{10} \to H_{10} + \Xi_1 - \Xi_0$$

$$H_{20} \to H_{20} + \Xi_2 \qquad H_{30} \to H_{30} + \Xi_3$$

which show how to choose the amplitudes Ξ_i to cancel the components H_{i0}. After this procedure, the resulting wave is replaced in Lorentz gauge (8.58) in order to obtain four restrictions for the $H_{\alpha\beta}$'s. Thus, it results that

$$0 = H_{11} + H_{22} + H_{33} \quad H_{11} = 0 \quad H_{12} = 0 \quad H_{13} = 0$$

This means that the genuine degrees of freedom reduce only to two, which are represented by the wave transversal part, H_{22}, H_{23}, H_{33}, subjected to the

---

[26] In Eqs. (8.55) and (8.57) the symbol $\Box$ indicates the operator $\eta^{kl}\,\partial_k\,\partial_l$, which does not have invariant character under general coordinate changes. In order to built a second order operator invariant under general coordinate changes, replace V^i in Eq. (8.36) with the gradient of an invariant O: $V^i = g^{ij}\,\partial_j\,O$. Thus it results that the Laplacian (Riemannian geometry) or the d'Alembertian (pseudo-Riemannian geometry) of O is $g^{ij}\,O_{,ij} = |g|^{-1/2}\,\partial_i|\,g|^{1/2}\,g^{ij}\,\partial_j\,O$.

[27] Under a gauge transformation it is $\eta^{kl}\,\tilde{h}_{kj,l} \to \eta^{kl}\,\tilde{h}_{kj,l} - \Box\xi_j$. Therefore, Lorentz gauge $\eta^{kl}\,\tilde{h}_{kj,l} = 0$ is reached if $\Box\xi_j = \eta^{kl}\,\tilde{h}_{kj,l}$. This equation does not completely determine ξ_j because any covector with zero d'Alembertian can be added to ξ_j.

condition of zero trace, $H_{22} + H_{33} = 0$. This way of fixing the gauge is called *TT- gauge* (transverse-traceless).

The particularly simple form adopted by the plane wave in this gauge leads to a result that seems strange at first sight: $\Gamma^i_{00} = 0$ for all value of i. This means that the timelike world lines $x^0 = \tau,\ x^\alpha = constant$ ($\alpha = 1, 2, 3$) are geodesic for the metric of this gravitational wave. Said in this way, it could be believed that particles initially at rest do not undergo any change due to the gravitational wave passing. However, the wave effects should not be read in terms of the chosen coordinates but in terms of the involved physical magnitudes. Instead of paying attention to the coordinates, it should be remarked that the metric oscillation modifies the *distances* between particles. As seen, only those distances that are perpendicular to the propagation direction will undergo changes. To study this effect it is convenient to distinguish two independent linear polarizations: (a) $H_{23} = 0,\ H_{22} = -H_{33} \neq 0$; (b) $H_{23} \neq 0,\ H_{22} = 0 = H_{33}$. A 45° rotation in the $(x^2,\ x^3)$-plane transforms each one of these polarizations in the other; then we can reduce our study to the understanding of the effect produced by the first polarization. In this case, the distances between particles placed along a line parallel to the x^2 axis will increase at the same time that the distances between particles arranged along the direction of the x^3 axis will decrease (and vice versa): the oscillations of distances are in counter-phase because it is $H_{22} = -H_{33}$. Owing to the wave passing, a ring of particles in the $(x^2,\ x^3)$-plane deforms to an ellipse whose axes oscillate in counter-phase along the directions $x^2,\ x^3$. The same effect is produced by the other linear polarization, but the ellipse axes are rotated in 45°. The change of distances due to the wave passing is reflected in the change of the travel time of a light ray making round trips between two particles.

degrees of freedom and automatic conservation

Certainly, the number of genuine degrees of freedom of the gravitational field is two, not only in the linearized version of the theory but also for the exact Einstein equations (8.46). In principle, there are ten independent Einstein equations to determine the ten independent components of the symmetric tensor g_{ij}. However, it would be disappointing that Einstein equations completely determine the metric tensor, because such situation would imply the determination of the coordinate system as well. Einstein equations should determine the components of metric tensor, but not beyond the freedom associated with coordinate changes. In other words, Einstein equations should determine the space-time *geometry* without getting involved with the coordinate system at all. The metric tensor resulting from Einstein equations should then keep a *gauge freedom* associated with the choice of the coordinate system. Remarkably this is what really happens, as a consequence of the fact that the left side in Eq. (8.46)—the *Einstein tensor* $G_{ij} \equiv R_{ij} - (1/2)\, g_{ij} R$—verifies the *automatic conservation*: $G^{ik}{}_{;k} \equiv 0$ (see Note 24). These equations are contracted Bianchi identities that play a role similar to that of Eq. (7.83) in electromagnetism. In fact, Eq. (7.83) are the covariant form of Maxwell's equations without sources (1B.1), which suggest writing the fields as derivatives of the potentials A^i (see Eq. (5.18)). This means that the *generalized* Bianchi identities (7.83) of electromagnetism

entail the relation (7.78) and the gauge freedom (7.87) generated by ξ. The existence of generalized Bianchi identities is characteristic of any theory whose action has gauge invariance. As it was shown in the linear approximation, gauge transformations have, in this case, four "generators" ξ_i. The free choice of coordinates makes possible to fix four components of the metric tensor, so leaving six components to describe the geometry. However the gauge freedom has not been completely fixed: as it happens in electromagnetism, each generator ξ_i alludes not to one but two spurious degrees of freedom; thus, the ten independent components of metric tensor g_{ij} contain only two genuine degrees of freedom.

To confirm this conclusion, let us first remark that $g_{00,00}$ does not appear in Riemann tensor (8.42); so it does not take part in Einstein equations.[28] This indicates that g_{00} is not a genuine dynamical variable and can be fixed by means of one of the four gauge transformations. We shall use the three remaining gauge transformations to choose the three components $g_{\mu 0}$ ($\mu = 1, 2, 3$) to be zero.[29] Therefore, Einstein equations will describe the dynamics of the six components $g_{\mu\nu}$ being left. But, in this gauge the four equations associated with Einstein tensor components G_{i0} do not contain temporal second derivatives $g_{\mu\nu,00}$. In fact, there is no presence of $g_{\mu\nu,00}$ in Einstein tensor components $G_{\mu 0} = R_{\mu 0}$ (note that $\Gamma^0{}_{\mu 0} = (1/2)\, g^{00}\, g_{00,\mu}$ in (8.44)); besides, the contributions $(1/2)\, g^{\mu\nu}\, g_{\mu\nu,00}$ appearing in $G_{00} = R_{00} - (1/2)\, g_{00}\, g^{ij}\, R_{ij} = (1/2)\,(R_{00} - g_{00}\, g^{\mu\nu}\, R_{\mu\nu})$ cancel out.[30] Therefore, the four Einstein equations associated with components G_{i0} are not dynamical equations in this gauge, because they do not contain temporal second derivatives. Thus they are four equations that constrain the possible initial values for $g_{\mu\nu}$ and $g_{\mu\nu,0}$, therefore reducing the number of degrees of freedom contained in the six components $g_{\mu\nu}$ to only two.

The automatic conservation $G^{ik}{}_{;k} \equiv 0$, which expresses the existence of gauge freedom, also means that Einstein equations *impose* the conservation of the energy–momentum tensor T^{ik}; otherwise, the equations would be inconsistent. Therefore, Einstein equations not only describe the dynamics of the geometry but also contain essential features of the behavior of its sources.

See Appendix

[28] Instead $h_{00,00}$ does appear in Eqs. (8.55) and (8.57) as a consequence of Lorentz gauge (8.52). Compare R_{ij} before and after the Lorentz gauge (Eqs. (8.49) and (8.53)).

[29] The vanishing of components $g_{\mu 0}$ ($\mu = 1, 2, 3$)—and then, the $g^{\mu 0}$'s as well—is reached when the coordinate lines $x^\mu = constant$ are orthogonal to the hypersurfaces $x^0 = constant$.

[30] $g^{00} = g_{00}{}^{-1}$ if $g_{\mu 0} = 0$.

Chapter 2

Which Geometry?

2.1 Physics or Geometry

2.1.1 *The heated plane*

In *La Science et l'Hypothèse* Henri Poincaré [68] argued for the 'passivity' of physical space. Since all measurements involve both physical and geometrical assumptions, Poincaré considered it meaningless to ask whether space was Euclidean or non-Euclidean. We might try to measure the sum of the angles of a triangle formed by three hill tops and check to determine whether their sum was greater or less than 180°.

In fact, Gauss attempted such a measurement. He measured the sum of the angles of a triangle formed by the three peaks of Broken, Hohehangen and Inselsberg. The sides of the triangle were 69, 85 and 197 km. Gauss determined that the sum exceeded 180° by 14″85. However, to the chagrin of Gauss, the experiment was inconclusive since the experimental error was greater than the excess he found. In fact, the sum could have as well as been less than 180°. The triangle was too small, since as Gauss realized, the defect is proportional to its area, and only a big triangle, of astronomical proportions, could be used to settle the question of whether the geometry of the universe is Euclidean or not.

Poincaré was more indecisive in that he reasoned that any defect which could be revealed could equally as well be the consequence of the fact that light rays do not always travel in straight paths. It is this type of reasoning that was used against Poincaré, and from being denied the discovery of relativity. For we have seen in 1.2.2 that many of the concepts that were attributed to Einstein rightly belong to Poincaré, such as the velocity addition theorem, for which uniform motion is undetectable as far as physical laws are concerned, and the axiom that nothing can travel faster

than light. His willingness to change a physical law so as to suit Euclidean geometry is responsible for his secondary role in twentieth century science. But not a word was muttered when Einstein [22] was found agreeing with Poincaré's philosophy.

To make his point, Poincaré considered an imaginary universe Ω in the interior of a sphere of radius R. In such a universe, at any point p, its temperature would be given by $T(p) = k(R^2 - r^2)$, where k is a positive constant and r is the Euclidean distance from the center of the sphere to the point p in question. He also assumed that the linear dimensions of the body vary with the temperature at the point where the body is found so that as one moves from the center of the body to the surface he becomes colder and contracts. In fact, it would take him an infinite amount of time to reach the surface. Even worse he cannot detect his shrinkage because the measuring sticks he uses shrink along with him. To our traveler, the universe appears infinite.

We know that in Euclidean space the shortest path between two points is a straight line. But, because of the shrinkage, *these geodesics, which are by definition the paths of shortest distance* between pairs of points in Ω, are not straight lines, but are curves bent inward toward the center of Ω. Actually, they are circular arcs that cut the boundary normally. This is shown in Fig. 2.1 where the bug's right legs are shorter than his left so even though he thinks he is traveling in a straight path, the unequal lengths of his legs cause him to follow a circular arc AB.

Fig. 2.1. A bug's life in the heated disk; 'hot' in the center and 'cold' on the disc.

However, to the bug, his right legs do not appear to be shorter than his left legs because his measuring tools also contract as things get colder. But, to us Euclideans, it *appears* that the bug's right legs are shorter than his left legs because we are using Euclidean measuring sticks.

So even though we owe this model of hyperbolic geometry to Poincaré, he failed to find it physically attractive. The question he posed "Which geometry is correct?" was answered by him with another question: "Which geometry is more convenient?" And unhesitatingly Poincaré clung to Euclidean geometry as the true geometry which Nature chooses. So that if we find a discrepancy between a physical law and Euclidean geometry we must be willing to change the former so as to preserve the latter. In effect, Poincaré was debasing his models of hyperbolic geometry, along with those of Beltrami and Klein, as having no physical relevance.

Suppose that we have to deal with a rather large metal sheet which is not at a uniform temperature. Take one edge of the sheet and label it the x-axis, and consider its normal y-axis to vary with temperature in the following way:

$$T = by - \frac{1}{p},$$

where b and p are constants. Suppose also that the metallic sheet is fixed in such a way that it cannot bend or buckle. Lastly, we are given a measuring stick made of another metal whose thermal coefficient of expansion is p. How can we use this stick to determine the nature of the geometry of the sheet?

It would be better to have a measuring rod whose coefficient of thermal expansion were zero, but not having one we are left to make measurements with this imperfect rod. We therefore inquire how to make *consistent* measurements. There are two ways:

(i) At some standard temperature, which we take to be zero degrees celsius, the measuring stick has a length ds. But because there will be points with higher temperatures, the true length at any point (x, y) will be

$$ds' = (1 + pT)ds = pby\, ds.$$

This choice allows us to maintain our Euclidean measure on the surface by allowing for a temperature correction factor pby. This is our physical law which allows us to preserve the Euclidean nature of the geometry.

(ii) We make measurements without taking into account the changes in the length of the rod. Here, we clearly rule out that there are changes in matter due to heat variations, and look to the geometry to make the necessary modifications.

If we opt for the second choice we realize that the x-axis represents absolute cold, which corresponds to a line at infinity. If we try to make measurements using a rod parallel to the y-axis we find that the stick will become shorter and shorter as it approaches the x-axis, so that it will appear as a line at infinity because it is infinitely far away.

The prime interest of a geometer is to create an object, such as a triangle, made up of the measuring sticks, that when moved over the surface remains congruent. We shall refer to such displacements as motions, of which we will be interested primarily in infinitesimal ones. But, we must first determine how we measure distance, or define a metric for the space. Wanting to keep as close as possible with a Euclidean measure we might try:

$$pby\, ds = \sqrt{(dx^2 + dy^2)}.$$

If we agree to a choice of units where $pb = 1$, then

$$ds = \frac{\sqrt{(dx^2 + dy^2)}}{y}. \tag{2.1.1}$$

This 'distance' increases without limit as $y \to 0$. For x constant, the 'distance' along vertical lines increases exponentially in comparison with its Euclidean counterpart. For example, the adjacent distances between $y = 1, \frac{1}{2}, \frac{1}{4}, \ldots$ at $x = 0$ are all equal.

We now want the invariance property of this metric to determine the permissible motions. Consider, for instance, a point transformation:

$$x' = x'(x, y), \quad y' = y'(x, y). \tag{2.1.2}$$

We want this point transformation to conserve distance; the condition is:

$$\frac{dx'^2 + dy'^2}{y'^2} = \frac{dx^2 + dy^2}{y^2}. \tag{2.1.3}$$

Obviously, this implies the invariance of distance, but we want something more. We want it also to preserve angles, meaning we want it to be conformal. For later use, observe that

$$\begin{aligned}
\frac{1}{y'^2}\left\{\left(\frac{\partial x'}{\partial x}\right)^2+\left(\frac{\partial y'}{\partial x}\right)^2\right\} &= \frac{1}{y^2},\\
\frac{\partial x'}{\partial x}\frac{\partial x'}{\partial y}+\frac{\partial y'}{\partial x}\frac{\partial y'}{\partial y} &= 0,\\
\frac{1}{y'^2}\left\{\left(\frac{\partial x'}{\partial y}\right)^2+\left(\frac{\partial y'}{\partial y}\right)^2\right\} &= \frac{1}{y^2}.
\end{aligned} \tag{2.1.4}$$

Now consider two infinitesimal displacements, (d_1x, d_1y) and (d_2x, d_2y) drawn from the point (x, y) and making an angle θ, and the corresponding ones (d_1x', d_1y') and (d_2x', d_2y') drawn from (x', y') making a corresponding angle θ'. In order for the transformation to be conformal, we require the cosines of the two angles,

$$\cos\theta = \frac{\frac{d_1xd_2x+d_1yd_2y}{y^2}}{\sqrt{\left[\left(\frac{d_1x^2+d_1y^2}{y^2}\right)\left(\frac{d_2x^2+d_2y^2}{y^2}\right)\right]}}, \tag{2.1.5a}$$

and

$$\cos\theta' = \frac{\frac{d_1x'd_2x'+d_1y'd_2y'}{y'^2}}{\sqrt{\left[\left(\frac{d_1x'^2+d_1y'^2}{y'^2}\right)\left(\frac{d_2x'^2+d_2y'^2}{y'^2}\right)\right]}}, \tag{2.1.5b}$$

to be equal, where we have divided numerator and denominator by y^2 and y'^2, respectively, in order to be able to use (2.1.3). That is, on account of (2.1.3) the denominators in (2.1.5a) and (2.1.5b) are equal so it remains only to show that the condition,

$$\frac{1}{y'^2}(d_1x'd_2x' + d_1y'd_2y') = \frac{1}{y^2}(d_1xd_2x + d_1yd_2y), \tag{2.1.6}$$

holds.

If we introduce,

$$dx' = \frac{dx'}{\partial x}dx + \frac{\partial x'}{\partial y}dy, \quad dy' = \frac{\partial y'}{\partial x}dx + \frac{\partial y'}{\partial y}dy,$$

into the left-hand side of (2.1.6) and use (2.1.4) it becomes evident that the left side coincides with the right side thereby establishing the conformality of the point transformation (2.1.2).

Regarding motions, it is easily seen that magnification $x \to ax$, with $a \geq 0$, and translation $x \to x + s$, with s real, are two possible motions. It is well-known that in a two-dimensional space, like the one we are considering, if there exist two independent motions then there must be a third. This third is called inversion and it states that if there are two points connected by a straight line to the origin of a circle whose circumference divides the two points then the product of the distances that the two points are from the origin is equal to the square of the radius. Inversion introduces the notion of anti-congruence.

The basic motions are most easily expressed in terms of complex variables $z = x + \mathrm{i}y$ and $w = x' + \mathrm{i}y'$, viz.

$$\begin{aligned} \text{translation:} \quad & w = z + s \quad (s \in \mathbb{R}) \\ \text{magnification:} \quad & w = az \quad (a \geq 0) \\ \text{inversion:} \quad & w = 1/\bar{z}, \end{aligned} \tag{2.1.7}$$

where $\bar{z}$ is the complex conjugate of z.

These three independent motions imply that any two-dimensional object in the space may be shifted, magnified and turned inside-out and still remain congruent if the number of inversions is even, or anti-congruent if the number of inversions is odd. These motions give the object complete freedom of movement.

If we generalize the concept of inversion to include the product of an inversion in the unit circle, a translation by an amount c,

$$w = \frac{z}{cz + 1},$$

and another inversion then we can construct a generic displacement as a product of the fundamental motions involving an even number of inversions. Such a generalized displacement will have the form [cf. (1.2.1)]:

$$w = \frac{az + b}{cz + d}, \tag{2.1.8}$$

where a, b, c, d are real numbers and the determinant $\Delta = ad - bc > 0$. The linear fractional transformation is known as a Möbius transform, and it will play a prominent role in what follows.

The Möbius transform (2.1.8) can be obtained by the following elementary motions [Archbold 70]:

$$\begin{aligned} z_1 &= cz, && \text{(magnification)} \\ z_2 &= z_1 + d, && \text{(translation)} \\ z_3 &= 1/z_2, && \text{(inversion)} \\ z_4 &= \frac{\Delta}{c} z_3, \end{aligned}$$

and so

$$w = \frac{a}{c} - z_4,$$

which is (2.1.8).

The displacement of any object in our space requires knowing the position of the object, and the alignment of a particular direction with that of an arbitrarily chosen direction in the space. For this to be accomplished we need three parameters, and the corresponding group is a three-parameter group. An object enjoying free mobility in such a space is a congruent space and its geometry is a congruent geometry. We will now dig deeper into the notions of these motions by transferring to the complex plane.

2.2 Geometry of Complex Numbers

2.2.1 *Properties of complex numbers*

An ordered pair (x, y) is called a complex number, $z = x + \mathrm{i}y$. The *modulus* of z is $r = \sqrt{(x^2 + y^2)}$. The number θ, defined by $\cos\theta = x/r$ and $\sin\theta = y/r$ is called the amplitude or *argument* (arg) of z. In terms of r and θ the complex number can be expressed as $z = r\mathrm{e}^{\mathrm{i}\theta} = r(\cos\theta + \mathrm{i}\sin\theta)$, and de Moivre's theorem follows:

$$(\cos\theta + \mathrm{i}\sin\theta)^n = \cos n\theta + \mathrm{i}\sin n\theta.$$

If z_1 and z_2 are any two complex numbers then

$$|z_1 z_2| = |z_1| \cdot |z_2|,$$
$$|z_1/z_2| = |z_1|/|z_2|,$$
$$\arg(z_1 z_2) = \arg z_1 + \arg z_2,$$
$$\arg(z_1/z_2) = \arg z_1 - \arg z_2.$$

The last two properties recall the property of logarithms, which we shall shortly return to.

Moreover, the product of a complex number z and its complex conjugate $\bar{z}$ is $z\bar{z} = |z|^2$. The square of the absolute value of the sum of two complex numbers is:

$$\begin{aligned}|z_1 + z_2|^2 &= (z_1 + z_2)(\bar{z}_1 + \bar{z}_2) = z_1\bar{z}_1 + z_2\bar{z}_2 + z_1\bar{z}_2 + \bar{z}_1 z_2 \\ &= |z_1|^2 + |z_2|^2 + z_1\bar{z}_2 + \bar{z}_1 z_2 \\ &= |z_1|^2 + 2\mathrm{Re}(z_1\bar{z}_2) + |z_2|^2 \\ &\leq |z|_1 + 2|z_1||z_2| + |z_2|^2 = (|z_1| + |z_2|)^2,\end{aligned}$$

since $\mathrm{Re}(z_1\bar{z}_2) \leq |z_1\bar{z}_2| = |z_1||z_2|$. Taking the positive square roots and observing that $|z| = |\bar{z}|$ gives the *triangle* inequality:

$$|z_1 + z_2| \leq |z_1| + |z_2|. \tag{2.2.1}$$

2.2.2 *Inversion*

The property of inversion can be stated as: If a circle of radius R has a center O and two points P and P' are inverse with respect to the circle then the following conditions must hold:

(i) O, P, P' lie on the same straight line;
(ii) O does not lie between P and P';
(iii) $OP \cdot OP' = r^2$.

To find the point of inversion P we construct a semicircle with diameter OP'. If Q is the point of intersection of this semicircle with the circle whose origin is 0 then P will be the foot perpendicular from Q to OP'. This is a

Fig. 2.2. Construction of the point of inversion P.

consequence of the fact that OQP' is a right triangle as shown in Fig. 2.2. Because OPQ will also be a right triangle,

$$\cos\vartheta = \frac{OP}{r} = \frac{r}{OP'},$$

and, consequently,

$$OP \cdot OP' = r^2; \tag{2.2.2}$$

O then is the center of inversion and the circle is called the circle of inversion.

These conditions can be simply stated as: If P and P' are represented by the complex number z and w, then

(i) $\arg w = \arg z$,
(ii) $|w| = r^2/|z|$,

where property (i) takes both properties (i) and (ii) of the above.

Given the point of inversion P we may calculate the coordinates of P', and *vice-versa*. From Fig. 2.3 it is apparent that the right triangles whose hypoteneuses are OP and OP' are similar so that

$$\frac{x}{y} = \frac{x'}{y'}. \tag{2.2.3}$$

Then since (2.2.2) holds,

$$(x^2 + y^2)(x'^2 + y'^2) = r^2.$$

Fig. 2.3. Circle of inversion for constructing the inverse P with respect to P'.

Introducing the value of y in (2.2.3) we have

$$x^2 + x^2 \cdot \frac{y'^2}{x'^2} = \frac{r^4}{x'^2 + y'^2},$$

or

$$x = \frac{x'r^2}{x'^2 + y'^2}, \quad y = \frac{y'r^2}{x'^2 + y'^2}.$$

These are the coordinates of the interior points which are fully symmetric to the exterior points,

$$x' = \frac{xr^2}{x^2 + y^2}, \quad y' = \frac{yr^2}{x^2 + y^2}.$$

Although the method of inversion has found extensive use in electrostatics, apparently introduced by Lord Kelvin, it seems to be relatively unknown in other branches of science. On closer inspection, however, it appears to have been employed for the first time in optics in a completely novel way by, the then twenty-three year old, Maxwell [Born & Wolf 59]. Since it combines Fermat's principle of least time, which we will need later on in Chapter 7, and inversion, we will now turn to a discussion of it.

2.2.3 *Maxwell's 'fish-eye': An example of inversion from elliptic geometry*

Light emitted by a point source at P_0 will propagate in a medium of index of refraction $\eta(x, y, z)$. Although an infinite number of rays have been emitted by our point source, only a finite number will be found to pass through any other point in the medium, with the exception of a point P_1 through which an infinite number of rays pass. Such a point is said to be a *stigmatic*, or sharp, image of P_0.

An optical instrument which images stymatically in three-dimensions is referred to as *absolute*. To every point P_0 in the *object* space there corresponds a stigmatic image P_1 in the *image* space. These points in the two spaces are said to be *conjugate* to one another. It was precisely Maxwell, in 1858, who proved that for an absolute instrument *the optical length of any curve in the object space is equal to the optical length of its image*, provided both spaces are homogeneous.

Maxwell provides us with a simple example of an absolute instrument in a medium which is characterized by a refractive index,

$$\eta(r) = \frac{1}{1 + (r/a)^2}\eta_0, \tag{2.2.4}$$

where r denotes the distance from a fixed point O, and η_0 and a are constants. It is commonly referred to as Maxwell's 'fish-eye' which he first studied in 1854.

According to Fermat's principle, light will propagate between any two points in such a way as to minimize (or at least to extremize) its travel time. In a system of varying index of refraction, (2.2.4), the true path will render the optical length,

$$\begin{aligned} I &= \int \eta(r)ds = \int \eta(r)\sqrt{(dr^2 + r^2 d\varphi^2)} \\ &= \eta_0 \int \frac{\sqrt{(dr^2 + r^2 d\varphi^2)}}{1 + r^2/a^2} = \eta_0 \int \frac{\sqrt{(1 + r^2\varphi'^2)}dr}{1 + r^2/a^2}, \end{aligned} \tag{2.2.5}$$

an extremum, where the prime indicates differentiation with respect to r.

Calling the integrand Λ, and noting that φ is a cyclic coordinate, i.e. φ is absent but its derivative is not, we immediately obtain a first integral of

the motion,

$$\frac{\partial \Lambda}{\partial \varphi'} = \frac{\eta(r) r^2 \varphi'}{\sqrt{(1 + r^2 \varphi'^2)}} = c = \text{const.}$$

Solving for φ', we get

$$\varphi = c \int^r \frac{dr}{\sqrt{(\eta^2(r) r^2 - c^2)}},$$

on integrating. To perform the integral it will be convenient to set $\rho = r/a$ and $\kappa = c/a\eta_0$. For then we find:

$$\begin{aligned}\varphi - \varphi_0 &= \int^\rho \frac{\kappa(1 + \rho^2) d\rho}{\rho\sqrt{(\rho^2 - \kappa^2(1 + \rho^2)^2)}} \\ &= \int^\rho \frac{d}{d\rho}\left[\sin^{-1}\left(\frac{\kappa}{\sqrt{(1 - 4\kappa^2)}} \frac{\rho^2 - 1}{\rho}\right)\right] d\rho,\end{aligned}$$

and, consequently, by inverting,

$$\sin(\varphi - \alpha) = \frac{c}{\sqrt{(a^2 \eta_0^2 - 4c^2)}} \frac{r^2 - a^2}{ar}, \tag{2.2.6}$$

where α is a constant of integration.

Expression (2.2.6) is the equation of a circle in polar coordinates. All rays through the fixed point, $P_0(r_0, \varphi_0)$, must be as such to keep the ratio,

$$\frac{r^2 - a^2}{r \sin(\varphi - \alpha)} = \frac{r_0^2 - a^2}{r_0 \sin(\varphi_0 - \alpha)},$$

constant. The fixed point $P_1(r_1, \varphi_1)$ must also satisfy this ratio for whatever α may be, and this leads to the conditions

$$r_0 r_1 = a^2, \quad \varphi_1 = \pi + \varphi_0. \tag{2.2.7}$$

All rays from a point P_0 meet at P_1 which lies on a line connecting P_0 to O. The points P_0 and P_1 lie on opposite sides of O such that $OP_0 \cdot OP_1 = a^2$. Consequently, Maxwell's fish eye is an absolute instrument where the image is an *inversion* since the first condition in (2.2.7) is the condition for inversion, (2.2.2). Only this time O is between the two points instead of condition 2 above.

For $\varphi = \alpha$ and $\varphi = \pi + \alpha$, $r = a$ and each ray emanating from a fixed point P_0 intersects the circle $r = a$ normally. All Euclidean circles orthogonal

Fig. 2.4. Maxwell's "fish-eye."

to the rim of the circle of radius $r = a$ are the routes of geodesics in the elliptic plane E. The rays emanating from any fixed point P_0 and coalescing at P_1, which lies on the line OP_0, are geodesics, or paths of shortest distance between the two points. Arcs of a circle replace straight lines in the elliptic plane. We shall return to this point shortly.

To transform the Eq. (2.2.6) from polar to Cartesian coordinates we set $x = r\cos\varphi$ and $y = r\sin\varphi$. We then obtain

$$y\cos\alpha - x\sin\alpha = \frac{c}{a\sqrt{(a^2\eta_0^2 - 4c^2)}}(x^2 + y^2 - a^2),$$

$$(x - b\sin\alpha)^2 + (y + b\cos\alpha)^2 = a^2 + b^2 = \frac{a^4}{4\kappa^2}, \tag{2.2.8}$$

where $b = (a/2c)\sqrt{(a^2\eta_0^2 - 4c^2)}$. According to the theorem of chords, all chords passing through a fixed interior point, in this case O, are divided into two parts whose lengths have constant product: $OP_0 \cdot OP_1 = a^2$. W thus have to set $b = 0$, so that the radius of the circle of inversion is exactly $a = 2c/\eta_0$.

If we do not distinguish between the flat metric and the index of refraction in (2.2.5), then we can write the metric as

$$d\bar{s}^2 = \eta^2(r)ds^2 = \frac{dr^2 + r^2d\varphi^2}{(1 + (r/r_0)^2)^2}, \tag{2.2.9}$$

Fig. 2.5. The magnification of the inner product as it is projected stereographically onto the Euclidean plane.

where we set the absolute constant $a = r_0$. A simple way to get new geometric structures is to distort old ones. The stereographic projection of the dot product of the tangent vectors $\tilde{\mathbf{x}}$ and $\tilde{\mathbf{y}}$ at a point p on the surface of a sphere S projects onto the Euclidean plane at a point q where $\mathbf{x}$ and $\mathbf{y}$ are the tangent vectors, as shown in Fig. 2.5. The relation between their inner products is given by the *stereographic* inner product distortion [O'Neill 66]

$$\mathbf{x} \cdot \mathbf{y} = \left(1 + \frac{x^2 + y^2}{r_0^2}\right) \tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}}, \tag{2.2.10}$$

and so transforms the Euclidean plane into the *stereographic plane* with constant, positive curvature, $1/r_0^2$.

To rationalize (2.2.10), we consider the inverse map of a plane onto a sphere, from a horizontal plane of height r_0 onto a sphere of radius r_0. This is given by the projection along the radius $(x, y, z) \mapsto (\lambda x, \lambda y, \lambda z)$, where $z = r_0$, the domain of the plane, and $(\lambda x)^2 + (\lambda y)^2 + (\lambda r_0)^2 = r_0^2$, the codomain of the sphere. Solving for λ results in:

$$\lambda = \frac{r_0}{\sqrt{(r_0^2 + x^2 + y^2)}}, \tag{2.2.11}$$

and, consequently, the stereographic inner product can be written as

$$\lambda \mathbf{x} \cdot \lambda \mathbf{y} = \tilde{\mathbf{x}} \cdot \tilde{\mathbf{y}},$$

which is again (2.2.10).

Stereographic projection was one of the topics covered by Riemann in his 1854 lecture for his *Habilitation*. Although he discusses a space of positive, constant, curvature, $1/r_0^2$, he was undoubtedly aware of what happens

when r_0 becomes imaginary. In such an event, the inner product (2.2.10) makes sense only when we restrict it to a disc $x^2 + y^2 < r_0^2$. Inside this region, the two-dimensional space is one of *negative*, constant, curvature. We shall come back to this in our discussion of the Poincaré disc model in Sec. 9.5.

Stereographic projection possesses two very remarkable properties:

(i) Circles on the sphere are mapped into lines or circles in the plane.
(ii) Angles are preserved: the angle formed from two intersecting circles on the sphere is the same as the angle formed from intersecting lines or circles in the plane that correspond to the former under stereographic projection.

Therefore, by sacrificing straight line geodesics we have been able to preserve angles so the stereographic projection is a *conformal map* of the surface. Maxwell, unwittingly, discovered that his expression for the refractive index, (2.2.4), was the dilatation factor in

$$d\bar{s} = \eta(r)ds, \tag{2.2.12}$$

in which the infinitesimal shape on the surface is represented in the map by a similar shape that differs from the original one only in size. The one on the stereographic plane is just η times bigger, and *the index of refraction is the stereographic magnification factor*! This was indeed a big fish to fry for the 23 year-old: he obtained an image as an inversion using stereographic projection. We will use the metric (2.2.12) in Chapter 7 to derive the tests of general relativity by identifying physically the index of refraction, η, which is the magnification factor of the flat metric, ds.

The essential point is that both the point source P_0 and its image point P_1 are on different collinear rays emanating from O, whereas in the case of inversion, a circle P_0 and its image P_1 are on the same ray emanating from O. This is guaranteed by the form of the index of refraction (2.2.4).

As we have just mentioned, we can get a surface of negative curvature, $-1/r_0^2 = 1/(\mathrm{i}r_0)^2$ by allowing the radius of the sphere to take on the *imaginary* value $\mathrm{i}r_0$. Instead of the index of refraction (2.2.4) we now have

$$\eta(r) = \frac{1}{1-(r/r_0)^2}\eta_0, \tag{2.2.13}$$

which obviously limits us to a (hyperbolic) disc $r < r_0$, which is the absolute constant of the space. Following the same procedure as before, we now find the equation of the circle

$$(x - \beta \sin \alpha)^2 + (y + \beta \cos \alpha)^2 = \beta^2 - r_0^2, \tag{2.2.14}$$

where $\beta = (r_0/2c)\sqrt{(r_0^2 n_0^2 + 4c^2)}$. The circle of inversion, C, has a center at (β, α), and its distance from the center of the hyperbolic disc is β. But, in order that (2.2.14) describe a circle, $\beta > r_0$, as can be seen in Fig. 2.6, the center of inversion must lie outside the hyperbolic plane, H. Thus, its center does not separate the source P_0 and its image P_1 along a common line uniting the three points, and, as a consequence P_0 and P_1 will not lie on geodesics arcs of a circle. So, it was not at all fortuitous that young Maxwell chose the form (2.2.4) for the index of refraction, and not (2.2.13).

In fact, as we approach the rim of H, which does not belong to H, the index of refraction (2.2.13) becomes infinite. Since the velocity of propagation is inversely proportional to the index of refraction, it will become very small in the limit. Clocks slow down and rulers shrink as they approach the rim when viewed from our Euclidean perspective. We might expect that this shrinking of rulers and slowing down of clocks to have something to do with space contraction and time dilatation.

This 'shrinkage' of rulers, and 'slowing down' of clocks is in direct contrast as to what happens in the stereographic, or elliptic, plane of constant

Fig. 2.6. In the case of inversion both the point and its image are on the same ray emanating from the center of the disc H.

Fig. 2.7. It appears that rulers get longer as they are moved further from the origin. However, the elliptic distance from x to y is exactly the same as that from X to Y.

positive curvature. The projection of points in the northern hemisphere X and Y are much further away from the origin than projections from the southern hemisphere, x and y, as shown in Fig. 2.7. The index of refraction (2.2.4) becomes smaller and smaller the farther we move away from the origin. This means that the velocity increases and clocks speed up, while rulers get longer as they move farther away from the origin. Large circles in the stereographic plane have very small stereographic arc-length since they correspond to small circles about the north pole of the sphere S.

In consideration of the relationship between hyperbolic and elliptic spaces we might expect phenomena such as time contraction and space dilatation to be characteristic of elliptic spaces when viewed from our Euclidean perspective. To an inhabitant of the plane, he would measure the same distance between x and y in Fig. 2.7, as he would measure between X and Y.

2.2.4 *The cross-ratio*

Now consider a circular arc, defined by $\arg[(z - z_1)/(z - z_2)] = \text{const}$. In addition let there be two fixed points on the arc P_1 and P_2 with P lying between them. We let P vary such that the angle, measured in radians, $\angle P_1 P_2 = \theta$ is constant. If P, P_1, P_2 are represented respectively by z, z_1, z_2 the necessary and sufficient condition that the angle remains constant, as P is varied, is:

$$\arg(z - z_1) - \arg(z - z_2) = \arg\left(\frac{z - z_1}{z - z_2}\right) = \theta.$$

If $0 < \theta < \pi$, the locus of P is the arc of a circle with endpoints P_1 and P_2. For the particular values $\theta = \pi/2$, the locus of P is a semi-circle, while for $\theta = \pi$ it is the segment P_1P_2.

Generalizing to four points lying on an arc we have: If points P_3 and P_4 lie on an arc whose endpoints are P_1 and P_2, then

$$\arg\left(\frac{z_3 - z_1}{z_3 - z_2}\right) = \arg\left(\frac{z_4 - z_1}{z_4 - z_2}\right),$$

or

$$\arg\left(\frac{z_3 - z_1}{z_3 - z_2} \cdot \frac{z_4 - z_2}{z_4 - z_1}\right) = 0,$$

where the z_i's represent the P_i's. But, this can only be if the number,

$$\frac{z_3 - z_1}{z_3 - z_2} \cdot \frac{z_4 - z_2}{z_4 - z_1},$$

is real and positive. This number is the *cross-ratio* of the four numbers z_1, z_2, z_3, z_4. Alternatively, if P_3 and P_4 lie outside of the arc segment P_1P_2, then

$$\arg\left(\frac{z_3 - z_1}{z_3 - z_2} \cdot \frac{z_4 - z_2}{z_4 - z_1}\right) = \pi,$$

and the corresponding cross-ratio is a negative real number.

The cross-ratio finds its origins in renaissance art where artists found it necessary to give depth to their two-dimensional drawings. If the points A, B, C, D lie on a line and the pairs of points A, B separate C, D then the cross-ratio,

$$\{A, B|C, D\} = \frac{AC}{BC}\Big/\frac{AD}{BD},$$

is positive, while if they do not then the cross-ratio is negative. *The cross-ratio of four points is the minimum number of points that is invariant under projection.*

A correspondence between two straight lines such that for all corresponding quadruples, A, B, C, D and A', B', C', D', their cross-ratios are equal, $\{A, B|C, D\} = \{A', B'|C', D'\}$ is called a *projective* correspondence. Since the ordinary projection of a line onto a line preserves the cross-ratio, it is an example of a projective correspondence. Such a correspondence is said to be *perspective*.

A perspective is merely a realistic representation of spatial depth on a plane. Yet, the method for correct perspective was awarded to the Florentine painter, Brunelleschi at the beginning of the fifteenth century. Alberti solved a special case, known as *costruzione legittima*, whereby nonhorizontal floor tiles are lined up on a base line with ever-progressing smaller tiles placed behind them and letting them converge to a vanishing point on the horizon as in Fig. 2.8.

The development of projective geometry followed, mainly through the work of Desargues, with the introduction of 'vanishing' points, or points at infinity where parallels meet, and transformations which change lengths and angles, i.e. projections. But, if length and angles are not invariant under projection, what is? Since it is possible to project any three points on a line onto any three others, this cannot be an invariant. The smallest number of points which is invariant is four, and the cross-ratio is a projective invariant.

Following the proof given by Möbius in 1827 that the cross-ratio is a projective invariant, we consider four points on a line A, B, C, D, and a point O not lying on the line as in Fig. 2.9. Drop a normal onto the line and let δ be its length. By computing the area of the triangles $\triangle OCA$, $\triangle OCB$, $\triangle ODA$ and $\triangle ODB$, first using the height δ and the bases AB, BC, DA, and DB, and then using the bases OA, and OB, and expressing the height in

Fig. 2.8. A tiling of the plane.

Fig. 2.9. Calculation of cross-ratio and perspectivity.

terms of the sines of the angle at O, we find

$$\frac{1}{2}\delta \cdot CA = \text{area } OAC = \frac{1}{2}OA \cdot OC \sin \angle COA,$$
$$\frac{1}{2}\delta \cdot CB = \text{area } OCB = \frac{1}{2}OB \cdot OC \sin \angle COB,$$
$$\frac{1}{2}\delta \cdot DA = \text{area } ODA = \frac{1}{2}OA \cdot OD \sin \angle DOA,$$
$$\frac{1}{2}\delta \cdot DB = \text{area } ODB = \frac{1}{2}OB \cdot OD \sin \angle DOB,$$

Taking the ratio of the first and second pairs, and dividing the former by the latter results in

$$\frac{CA}{CB}\Big/\frac{DA}{DB} = \frac{\sin \angle COA}{\sin \angle COB}\Big/\frac{\sin \angle DOA}{\sin \angle DOB}.$$

Observing that any other four points A', B', C', D' in perspective with the original points A, B, C, D, with the same external point O, will have the same central angle at O, shown in Fig. 2.9, and, consequently, will have the same cross-ratio.

Projective transformations, or collineations as they are sometimes referred to, can map parallel lines onto intersecting lines thereby providing a sense of depth, like the converging parallel lines in Fig. 2.8. In order to define a projective transformation, we must add points 'at infinity.' These are necessary in order to insure the one-to-one correspondence that arises in connection with the central projection of a plane onto a plane in which

some of the points of the first plane have no images. The straight lines of one that intersect the plane correspond to points of intersection with the plane, while those lines parallel to the plane are new points, called points at infinity where parallels meet. For when the straight line that intersects the plane becomes closer and closer to a parallel line, its point of intersection recedes to infinity. The Euclidean plane is transformed into the projective plane by the addition of points at infinity.

The logarithm of the cross-ratio measures hyperbolic distance. Because of the logarithmic form it would not satisfy the triangle inequality, (2.2.1). It is well-known that logarithmic equations of state in thermodynamics [Lavenda 09], and logarithmic measures of divergence in information theory [Kullback 59], have all the topological requisites of a distance except that of the triangle inequality. However, a remarkable property of the cross-product enables the hyperbolic distance to satisfy the triangle inequality, and, therefore, be considered as a *bona fide* distance.

Consider four collinear points with a and b between x and y with b between a and x. The cross-ratio,

$$\{a, b|x, y\} > 1,$$

unless $a = b$. If d is some other interior point,

$$\{a, d|x, y\} \cdot \{d, b|x, y\} = \{a, b|x, y\}, \tag{2.2.15}$$

and the cross-ratio is associative. Since the distance is the logarithm of the cross-ratios, it is precisely this last property that would lead one to believe that the triangle inequality cannot be satisfied. But wait a moment.

What happens if we shorten the interval, say to some x' lying between b and x. It can be shown that [Buseman & Kelly 53]:

$$\{a, b|x', y\} > \{a, b|x, y\}. \tag{2.2.16}$$

So anytime we shorten the interval we increase the cross-ratio, and, consequently, the distance from a to b is also increased.

To establish the triangle inequality consult Fig. 2.10. The perspectivity of the lines $\overline{uv}$ and $\overline{xy}$ from the pole, p, and the inequality (2.2.16) give

$$\{a, c|u, v\} = \{a, d|x', y'\} \geq \{a, d|x, y\}.$$

Fig. 2.10. The four points u, a, c, v and a, d, x', y' from point p have the same angles, hence, have the same cross-ratio. This also is true for c, b, w, z and d, b, x', y'.

Likewise, the perspectivity of $\overline{wz}$ and $\overline{xy}$, together with inequality (2.2.16), give

$$\{c, b|w, z\} = \{d, b|x', y'\} \geq \{d, b|x, y\}.$$

Taking the product of the two inequalities, and using property (2.2.15), result in

$$\{a, c|u, v\} \cdot \{c, b|w, z\} \geq \{a, d|x, y\} \cdot \{d, b|x, y\} = \{a, b|x, y\}.$$

Finally, forming the hyperbolic distances by taking the logarithm of both sides yields the triangle inequality,

$$h(a, c) + h(c, b) \geq h(a, b), \tag{2.2.17}$$

for the hyperbolic distance as the logarithm of the cross-ratio.

2.2.5 *The Möbius transform*

The properties of the Möbius transform that we discuss here will be used in Chapter 8, especially in Sec. 8.2.

2.2.5.1 *Invariance of the cross-ratio*

We will now show that the Möbius transform leaves the cross-ratio invariant. It is this property that Poincaré used, to show that all the cells of the tessellations in the hyperbolic plane are of equal size.

Take all four numbers z_1, z_2, z_3, z_4 to be different, and $cz + d \neq 0$ for any of them.

If

$$w_i = \frac{az_i + b}{cz_i + d},$$

$i = 1, \ldots, 4$, the w_i are all different and their differences are given by:

$$w_1 - w_2 = \Delta(z_1 - z_2)/(cz_1 + d)(cz_2 + d),$$

$$w_2 - w_3 = \Delta(z_2 - z_3)/(cz_2 + d)(cz_3 + d),$$

with Δ denoting, again, the determinant. Dividing the first by the second,

$$\frac{w_1 - w_2}{w_2 - w_3} = \frac{z_1 - z_2}{z_2 - z_3} \cdot \frac{cz_3 + d}{cz_1 + d}.$$

Likewise,

$$\frac{w_1 - w_4}{w_4 - w_3} = \frac{z_1 - z_4}{z_4 - z_3} \cdot \frac{cz_3 + d}{cz_1 + d},$$

and again dividing the first by the second,

$$\frac{w_1 - w_2}{w_2 - w_3} \Big/ \frac{w_1 - w_4}{w_4 - w_3} = \frac{z_1 - z_2}{z_2 - z_3} \Big/ \frac{z_1 - z_4}{z_4 - z_3}.$$

The left- and right-hand sides are the cross-ratios of four numbers, and they are equal. This shows that the Möbius transform preserves cross-ratios.

2.2.5.2 *Fixed points*

A fixed point occurs when $w = z$. Fixed points are, therefore, determined by the equation

$$cz^2 + (d - a)z - b = 0.$$

It is not difficult to see that the only Möbius transform with more than two fixed points is the identity transform. For if $a = d$ and $b = c = 0$, every point is fixed. The transformation reduces to $w = z$, or the identity

transformation. Now, if $a = d$, $b \neq 0$, and $c = 0$, the quadratic has one root, i.e. ∞, which is the only fixed point. Further, if $c = 0$, $a \neq d$, and $b \neq 0$, the quadratic has distinct roots, $b/(a-d)$ and ∞. Now, assume that $c \neq 0$ and δ is either of the square roots of the discriminant, $(a-d)^2 + 4bc$. If $\delta \neq 0$, the quadratic has two distinct roots, $(a - d \pm \delta)/2c$. Rather, if $\delta = 0$, the roots coalesce to a single fixed point $(a-d)/2c$. Hence, we have shown that there cannot be more than two fixed points of a Möbius transformation.

2.2.5.3 *Associativity*

The Möbius transformation is also associative, just like the cross-ratio, (2.2.15). That is, if T_1 transforms z_1 into z_2 and T_2 transforms z_2 into z_3, then the product T_1T_2 transforms z_1 into z_3.

Let T_1 be the Möbius transform, $w = (az + b)/(cz + d)$, and T_2 be the transform, $w = (Az + B)/(Cz + D)$, then their product, T_1T_2 is defined as

$$w = \frac{A[(az+b)/(cz+d)] + B}{C[(az+b)/(cz+d)] + D},$$

which has the same form

$$w = \frac{(Aa + Bc)z + (Ab + Bd)}{(Ca + Dc)z + (Cb + Dd)}.$$

Since the determinant is the product of determinants $\Delta_1\Delta_2 = (AD - BC)(ad - bc)$, and does not vanish, it makes T_1T_2 also a Möbius transformation.

A special product transformation will be of importance in our further developments; that is, when the product $T_1T_2 = I$, the identity transformation. The identity $w = z$ will result only when the following conditions are met

$$Aa + Bc = Cb + Dd,$$

$$Ab + Bd = 0,$$

$$Ca + Dc = 0.$$

This will happen only when the ratios $A:B:C:D$ are the same as $d: -b: -c: a$. Then there is a unique transform T_2 which has the Möbius transform,

$$w = \frac{dz - b}{-cz + a}.$$

It is the *inverse* to T_1, and is written as T_1^{-1}. Hence, T_1 transforms z_1 into z_2, and T_1^{-1} transforms z_2 back into z_1. Moreover, if it happens that $a+d=0$, T_1 and T_1^{-1} are the same, and T_1 is called *involutory*, since it is its own inverse.

2.2.5.4 *Transformations for which the unit circle is invariant*

These transformations are particularly interesting for they correspond to the Lorentz transformations in relativity. Considering complex coordinates on the unit disc, a Lorentz transformation corresponds to a Möbius transformation,

$$w = \frac{az + \bar{c}}{cz + \bar{a}}, \tag{2.2.18}$$

for which $|\bar{a}| > |\bar{c}|$, so that their ratio, $|\bar{c}/\bar{a}|$ will be a point in the interior of the unit disc. This is a necessary and sufficient condition that w maps the interior of the unit disc onto its interior [Schwerdtfeger 62].

A Möbius transform which transforms three distinct points of a unit circle into three other distinct points of the circle it must, obviously, transform the unit circle into itself since if z is a circle or a line, so too will be w.

If the Möbius transform, $w = (az+b)/(cz+d)$ transforms the unit circle into itself, $|w| = 1$, implying $|az + b| = |cz + d|$. The latter condition must be the same as $|z| = 1$. Now, the condition $|az + b| = |cz + d|$ is the same as

$$|z + b/a| = |c/a| \cdot |z + d/c|.$$

This is the equation of a circle having a pair of inverse points $-b/a$ and $-d/c$. We know that the two inverse points must be of the form $z = 1/\bar{z}$, which implies $b/a = \bar{c}/\bar{d}$.

As a special case we can set $b = \bar{c}$ and $d = \bar{a}$. For then, the Möbius transform which carries the unit circle into itself will be of the form (2.2.18). Inverting it we get

$$z = \frac{\bar{a}w - \bar{c}}{-cw + a}.$$

The family of circles $|z| = \kappa > 0$, where κ is real, is transformed into the coaxial circle: $|\bar{a}z - \bar{c}| = \kappa|cz - a|$. Coaxial circles are a family of circles such that any pair has the same radical axis. The radical axis is the line passing through the two points of intersection of a pair of circles, as the line PQ in

Fig. 8.1. The origin, which is a circle of radius $\kappa = 0$, is transformed into $\bar{c}/\bar{a}$, which lies inside the unit circle when $|c| < |a|$, and outside of it when $|c| > |a|$. The condition that the determinant must not vanish, $ad - bc \neq 0$, prohibits the case $|c| = |a|$.

2.3 Geodesics

Returning to our hyperbolic model of the heated plane, we have

$$s = \int_{p_1}^{p_2} \frac{\sqrt{(dx^2 + dy^2)}}{y} = \int_{p_1}^{p_2} \frac{1}{y} \left[1 + \left(\frac{dy}{dx} \right)^2 \right]^{1/2} dx, \tag{2.3.1}$$

as the distance between two points p_1 and p_2. The pre-factor has the form of a varying index of refraction. For if we suppose that at the Earth's surface $y = 0$, the index of refraction $\eta(y)$ will be a function of height y only. The propagation time, τ along a ray connecting two endpoints p_1 and p_2 will be given by Fermat's principle of least time:

$$c\tau = \int_{p_1}^{p_2} \eta(y) \sqrt{(1 + y'^2)} dx, \tag{2.3.2}$$

where the prime denotes differentiation with respect to the independent variable, x. The product $c\tau$ is known as the optical path length, where c is the velocity of light in vacuum. According to Fermat's principle of least time, the optical path length is stationary for the true ray path.

In terms of the integrand of (2.3.2),

$$\Lambda(y, y') = \eta(y) \sqrt{(1 + y'^2)}, \tag{2.3.3}$$

the Euler–Lagrange equation can be written as

$$\Lambda - y' \frac{\partial \Lambda}{\partial y'} = C, \tag{2.3.4}$$

where C = const is a first integral of the motion. Explicitly, the Euler–Lagrange equation (2.3.4) is

$$\frac{\eta}{\sqrt{(1 + y'^2)}} = C. \tag{2.3.5}$$

So, the constant C is the value of the index of refraction where the ray becomes horizontal. The angle, θ, formed between the tangent to the ray

Fig. 2.11. Derivation of Snell's law.

and the normal to the ray, shown in Fig. 2.11, is given by

$$\theta = \arcsin(dx/\sqrt{(dx^2 + dy^2)}) = \arcsin(1/\sqrt{(1 + y'^2)}),$$

so that the Euler–Lagrange equation (2.3.5) coincides with Snell's law,

$$\eta(y) \sin\theta = C. \tag{2.3.6}$$

According to Snell's law, the sines of the angles which the incident θ_i and transmitted θ_t rays make with the normal to an interface between two different media are proportional, i.e.

$$\frac{\sin\theta_i}{\sin\theta_t} = \eta, \tag{2.3.7}$$

where η is the relative index of refraction of the two media. Expression (2.3.6) generalizes Snell's law to the case where the index of refraction is a function of the height.

Ordinarily, the index of refraction decreases with altitude, and this is borne out by the heated plane model since upon comparing terms in the integrands of (2.3.1) and (2.3.2) we find $\eta = 1/y$, and, consequently, $d\eta/dy < 0$. The true ray that will connect the two points will be concave: Light minimizes its propagation time by arching its path upwards between the endpoints, like a cat ready to attack. As a result, objects do not appear to be where they are but are a little bit lower than our line of sight.

Fig. 2.11 – Derivation of Snell´s law → Estudar a curvatura do gráfico, muito interessante. Usar como referencial para checagem de ponto de contato.

In contrast, the index of refraction will be an increasing function of height in inversion layers where mirages are formed. The ray is now convex and the images will be higher than our line of sight. In both cases, these distortions are caused by the non-Euclidean nature of the geometry. This will be a recurrent theme throughout.

Even without making the integral (2.3.1) stationary we can get some remarkable properties about hyperbolic geometry, undoubtedly the most important of which is the angle of parallelism. Transforming to polar coordinates, and considering the arc γ to increase the angle from α to $\pi/2$ we get

$$\int_\gamma \frac{\sqrt{(dx^2+dy^2)}}{y} = \int_\alpha^{\pi/2} \frac{\sqrt{(r'^2+r^2)}}{r\sin\theta}d\theta$$
$$\geq \int_\alpha^{\pi/2} \frac{d\theta}{\sin\theta} = -\ln\tan(\alpha/2), \qquad (2.3.8)$$

where the prime now stands for differentiation with respect to the independent variable, θ.

If we set (2.3.8) proportional to the minimum distance from a point P, using the perpendicular distance d, to a line ℓ, as shown in Fig. 2.12, we have one of the most remarkable formulas in all of mathematics. The number α of radians in the *angle of parallelism* depends only on the distance d from P to Q and not on the particular line ℓ, or the particular point P. The formula was discovered independently by J. Bolyai and N. Lobachevsky. In Euclidean geometry the rays emanating at P must coincide, so α, which is usually written as $\Pi(d)$ in the literature, is always a right angle. However, under Lobachevsky's postulate these lines are distinct and the angle $\Pi(d)$ is necessarily acute. It is a function only of the hyperbolic distance d.

Fig. 2.12. Angle of parallelism.

The Euler–Lagrange equation which renders the integral (2.3.1) stationary is:

$$y'' + \frac{1 + y'^2}{y} = 0.$$

The solution to this equation is a family of circles

$$(x - a)^2 + y^2 = c^2,$$

whose centers lie on the x-axis, where a and c are constants of integration. Restricting ourselves to the half-circles located in the upper half-plane will give us the Poincaré half-plane model. The semi-circles will be the geodesics of our hyperbolic space.

If the plane were Euclidean, we could draw only one line through any given point parallel to a given straight line. This is Euclid's fifth postulate. In this plane there would be only one geodesic through a given point that would be parallel to another given geodesic. Not so in our heated plane! Because the geodesics are semi-circles, all geodesics through a point P not lying on the geodesic g in Fig. 2.13 are parallel to g, even h_1 and h_2, which are tangent to it at points U and V, because those points have been excluded by considering them infinitely far away, i.e. points at infinity.

To any student of geometry, this smacks of Lobachevsky geometry, who only claimed that *there exist two lines parallel to a given line through a given point not on the line*. However, this does not mean that he did not recognize that there were infinitely many non-intersecting lines. His parallel

Fig. 2.13. The number of lines passing through P that are hyperparallel to the line g are infinite. The lines h_1 and h_2 are limiting parallel to g, while the others are hyperparallel to g.

property is what is now usually referred to as 'asymptotically parallel' or 'horoparallel.'

Here, Lobachevsky's statement is due to the peculiar nature of the Poincaré half-plane model. Nevertheless, the half-plane model illustrates the hallmark of Lobachevskian geometry: the sum of the angles of a triangle are less than two right angles.

The heated plane model also illustrates other properties of projective geometry. We substitute the positive square root, $\sqrt{[c^2 - (x-a)^2]}$ for y in (2.3.1) and determine the distance s between two points x_1 and x_2 as

$$\begin{aligned} s &= \int_{x_1}^{x_2} \frac{c}{c^2 - (x-a)^2} dx \\ &= \frac{1}{2} \int_{x_1}^{x_2} \left\{ \frac{1}{c + x - a} + \frac{1}{c - x + a} \right\} dx \\ &= \frac{1}{2} \ln \left[\frac{x_2 - (a-c)}{(a+c) - x_2} \cdot \frac{(a+c) - x_1}{x_1 - (a-c)} \right]. \end{aligned} \tag{2.3.9}$$

Now, let us define two other x-coordinates, x_3, x_4 with $x_4 > x_3$, as the points where the geodesics intersect the x-axis, i.e. $x_3 = a - c$ and $x_4 = a + c$. Substituting these values into (2.3.9) results in

$$s = \frac{1}{2} \ln \left(\frac{x_2 - x_3}{x_4 - x_2} \cdot \frac{x_4 - x_1}{x_1 - x_3} \right). \tag{2.3.10}$$

This is precisely the logarithm of the cross-ratio,

$$\frac{x_2 - x_3}{x_4 - x_2} \cdot \frac{x_4 - x_1}{x_1 - x_3},$$

of four ordered points, x_1, x_2, x_3, x_4. For fixed endpoints x_3 and x_4, (2.3.10) is the hyperbolic distance between x_1 and x_2, which we know by (2.2.17) satisfies the triangle inequality.

2.4 Models of the Hyperbolic Plane and Their Properties

In the half-plane model, studied at the beginning of this chapter, we found it equipped with the distance function $ds = \sqrt{(dx^2 + dy^2)}/y$. This is one *model* of the hyperbolic plane because anything with the same metric is also a viable model of the hyperbolic plane.

In search of these other models, we take our cue from Euclidean and spherical geometries where equivalent metrics, or isometries, are found by using complex functions. In terms of the complex number, $z = x + \mathrm{i}y$, the distance $ds = \sqrt{(dx^2 + dy^2)}/y$ becomes $|dz|/\mathrm{Im}\, z$. The map from the half-plane to the disc is

$$w = \frac{\mathrm{i}z + 1}{z + \mathrm{i}}, \quad \text{or} \quad z = \frac{-\mathrm{i}w + 1}{w - \mathrm{i}},$$

so that

$$\begin{aligned} ds = \frac{|dz|}{\mathrm{Im}\, z} &= \left| d\left(\frac{\mathrm{i}w + 1}{w - \mathrm{i}}\right)\right| \Big/ \mathrm{Im}\left(\frac{-\mathrm{i}w + 1}{w - \mathrm{i}}\right) \\ &= \frac{2|dw|}{|w - \mathrm{i}|^2} \Big/ \mathrm{Im}\frac{(1 - \mathrm{i}w)(\bar{w} + \mathrm{i})}{|w - \mathrm{i}|^2} \\ &= \frac{2|dw|}{1 - |w|^2}. \end{aligned} \tag{2.4.1}$$

Thus, we have two models already of the hyperbolic plane:

- the upper half-plane model with distance $ds = |dz|/\mathrm{Im}\, z$, where the 'lines' are semi-circles perpendicular to the real axis, as in Fig. 2.13, and angles which are the same as Euclidean angles; and
- the open disc model with metric, (2.4.1), and 'lines' that are circular arcs orthogonal to the boundary, as shown in Fig. 2.6, with angles the same as Euclidean angles.

The reason for conformality of the Poincaré disc model is that it took two inversions to go from the half-plane to the disc. We will soon meet yet another disc model which straightens out the circular arcs at the cost of losing angle invariance.

The attribute of having a *circle at infinity* as a natural boundary is that the points on the disc are actually located at infinity as our inhabitants of the unit disc, whom we shall refer affectionately to as 'Poincarites,' know.[a] The distance from the origin to any point tends to infinity as the point tends to 1. Lines, or rather circular arcs, which have a common point on the circle

[a]The circle at infinity will take on a physical vest when it is identified as the limit of the inner solution to the Schwarzschild metric in Sec. 9.10.3. The name 'Poincarites' was probably first used by Needham [97].

at infinity are known as *asymptotic* lines. The point where they meet is not a point belonging to the lines, but, rather, a limit point because points are at 'infinity.' In contrast, ultraparallels are circular arcs which cut the circle at infinity but have no common point.

The distinction between these two lines in the unit disc is far from academic. A product of reflections in ultraparallel lines constitutes a *translation*, whereas a product of reflections in asymptotic lines is a 'limit' rotation. Limit rotations on the disc are circles tangent to the circle at infinity, and are known as *horocycles*, or 'limit' cycles. An amazing find was that a horocycle, or a horosphere in three-dimensions, is a circle at infinity that obeys Euclidean, and *not* a hyperbolic, geometry. This discovery was made by Wachter, a student of Gauss, way back in 1816. It will allow us to use Euclidean geometry to determine the properties of the hyperbolic plane, notably the angle of parallelism and the necessity of introducing an absolute constant, or a unit of measure, which is completely foreign to Euclidean geometry.

The horocycle, or circle whose center is at infinity, i.e. on the unit disc, is most clearly seen considering the 'pseudosphere.' Of all the mappings of constant negative curvature on the unit disc, it is only the middle figure in Fig. 2.14, which has been adapted from Klein's 1928 book on non-Euclidean geometry, that shows the horocyles as dashed lines. The solid lines are the image of one turn of the covering of the pseudosphere. All three mappings show that surfaces of constant negative curvature are mapped only onto part of the disc.

We postpone a discussion of some of the remarkable properties of the pseudosphere, which is to hyperbolic geometry what the plane and sphere are to Euclidean and elliptic geometry, respectively, and use the following property of horocycles to derive the angle of parallelism.

> The ratio of any two concentric limiting arcs cut by radii depends only on the distance between them and not on their size or where they are located in the hyperbolic plane.

It is by no means an understatement to say that all the trigonometric relations of hyperbolic geometry follow from the fact that the ratio of concentric limiting arcs l and m, with $l > m$, intercepted between two radii is

Fig. 2.14. Surfaces of negative constant curvature that are mapped onto part of the hyperbolic plane. The middle figure is the mapping of a pseudosphere that produces horocycles as dashed curves.

given by

$$l/m = e^{a/\kappa}, \tag{2.4.2}$$

where a is the distance between the arcs and κ is a positive (absolute) constant.

In Fig. 2.15 the arcs l, m, and n are cut by two radii. The distance between the first two is a, while the distance between the second and third arcs is b. We know that the ratios depend on the distance between them but

Fig. 2.15. The ratio of concentric limiting arcs depends only on the distance between them.

we do not know the functional form. That is,

$$l/m = f(a), \quad m/n = f(b), \quad l/n = f(a+b),$$

where f is a positive, and increasing function.

These relations suggest the functional relation,

$$f(a) \cdot f(b) = f(a+b).$$

Such a functional relation can only be satisfied by an exponential function. The transfer from any exponential $g > 1$ to the constant e entails introducing an absolute constant κ such that

$$g^a = (\mathrm{e}^{\ln g})^a = \mathrm{e}^{a/\kappa},$$

and on account that $g > 1, \kappa > 0$.

If we go back to the pseudosphere, we find that for any two points on its surface, the following remarkable relationship holds

$$x^2 + y^2 < \kappa^2.$$

When we go to plot these points on a Euclidean plane, as in Fig. 2.14, they are constrained to lie within a circle of radius κ. All points on the entire pseudosphere are thus constrained to lie within a circle of radius κ on a Euclidean plane.

This radius is called the *radius of curvature*, or *space constant*, and is an absolutely determined length. It is the analog of the radius of a sphere in spherical geometry under the transform $\kappa \to \mathrm{i}\kappa$. And although it is absolutely determined, its magnitude will depend upon the units chosen.

Fig. 2.16. Using Euclidean geometry to derive the angle of parallelism by considering concentric limiting arcs.

The arc lengths $C'B'$ and CB belong to two concentric horocycles in Fig. 2.16. The angle at C' is a right angle so that by Euclidean geometry $B'C' = l \sin\beta$ and $AC' = l\cos\beta$. The distance between the concentric arcs is

$$e^{b/\kappa} = e^{CC'/\kappa} = \frac{l}{B'C'} = \frac{l}{l\sin\beta} = \csc\beta.$$

Now, the ratio of the concentric limiting arcs $l + AC'$ and l is [Kulczycki 61]

$$e^{a/\kappa}/e^{b/\kappa} = \frac{l + AC'}{l} = 1 + \cos\beta,$$

and consequently,

$$e^{a/\kappa} = \frac{1+\cos\beta}{\sin\beta} = \cot(\beta/2).$$

Denoting $\beta = \Pi(a)$ as the angle of parallelism, which can only depend on the hyperbolic distance a, we obtain the Bolyai–Lobachevsky formula,

$$\tan\frac{\Pi(a)}{2} = e^{-a/\kappa}. \tag{2.4.3}$$

Euclidean geometry can be used in the hyperbolic plane to derive non-Euclidean results by considering the properties of concentric horocycles, and from their property (2.4.2) all the trigonometric formulas of hyperbolic geometry follow.

Now consider $M_1(x_1, y_1)$ and $M_2(x_2, y_2)$ as any two points on a horocycle lying in the unit disc. Let $M(x, y)$ be any point on the arc M_1M_2. With

Fig. 2.16 → estudar a curvatura e o seu limite. Interessante!!!

$M_1M/MM_2 = \lambda$, the relation between the coordinates are known to be

$$x = \frac{x_1 + \lambda x_2}{1+\lambda}, \quad y = \frac{y_1 + \lambda y_2}{1+\lambda}. \tag{2.4.4}$$

The values λ_1 and λ_2 will be the roots of the unit disc,

$$x^2 + y^2 = 1, \tag{2.4.5}$$

that is when M coincides with either P or Q on the boundary. Introducing (2.4.4) into (2.4.5),

$$(x_1 + \lambda x_2)^2 + (y_1 + \lambda y_2)^2 - (1+\lambda) = 0,$$

and defining

$$\Omega_{11} = x_1^2 + y_1^2 - 1, \quad \Omega_{22} = x_2^2 + y_2^2 - 1,$$
$$\Omega_{22} = x_1x_2 + y_1y_2 - 1,$$

so that the former equation can be written as the quadratic equation,

$$\Omega_{22}\lambda^2 + 2\Omega_{12}\lambda + \Omega_{11} = 0.$$

The ratio of the roots to this quadratic,

$$\lambda_{1,2} = \frac{-\Omega_{12} \pm \sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}{\Omega_{22}},$$

is the cross-ratio,

$$\{M_1, M_2|P, Q\} = \frac{\lambda_2}{\lambda_1} = \frac{\Omega_{12} + \sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}{\Omega_{12} - \sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}.$$

Thus, the distance between the two points M_1 and M_2 is:

$$\begin{aligned} s(M_1, M_2) &= \frac{\kappa}{2} \ln\left(\frac{\Omega_{12} + \sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}{\Omega_{12} - \sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}\right) \\ &= \kappa \tanh^{-1}\left(\frac{\sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}{\Omega_{12}}\right), \end{aligned}$$

where κ is the absolute constant.

We now transfer this result to velocity space. Let u and v be velocities, and s becomes relative velocity, w. The equation for the unit disc transforms into

$$u^2 + v^2 = c^2,$$

where c is the speed of light. Let us consider that v is infinitesimally close to u such that $v = u + du$. Now,

$$\Omega_{11} = u^2 + v^2 - c^2, \quad \Omega_{22} = du^2 + dv^2,$$
$$\Omega_{12} = u\,du + v\,dv,$$

and for small arguments, the inverse hyperbolic tangent can be approximated by the argument itself, so that

$$\begin{aligned} dw^2 &= \frac{\sqrt{(\Omega_{12}^2 - \Omega_{11}\Omega_{22})}}{\Omega_{22}} \\ &= c^2 \frac{(u\,du + v\,dv)^2 - (u^2 + v^2 - c^2)(du^2 + dv^2)}{(u^2 + v^2 - c^2)^2} \\ &= c^2 \frac{c^2(du^2 + dv^2) - (v\,du - u\,dv)^2}{(u^2 + v^2 - c^2)^2}, \end{aligned} \tag{2.4.6}$$

Equation (2.4.6) is the famous Beltrami metric, but whose derivation we followed was that by Klein [71].

If the velocities are infinitesimally close to one another, such that $v = u + du$ then (2.4.6) becomes

$$dw^2 = c^2 \left\{ \frac{c^2(d\mathbf{u})^2 - (\mathbf{u} \times d\mathbf{u})^2}{(c^2 - u^2)^2} \right\},$$

or

$$= c^2 \left\{ \frac{(d\mathbf{u})^2}{c^2 - u^2} + \frac{(\mathbf{u} \cdot d\mathbf{u})^2}{(c^2 - u^2)^2} \right\}. \tag{2.4.7}$$

We will come across the Beltrami metric on numerous occasions, for example in the radiation pressure in Sec. 4.2.4, on uniformly rotating disc in Sec. 9.6, and in the Thomas precession in Sec. 10.1, which was discovered by Borel.

For finite difference between the velocities **u** and **v**, the relative velocity **w** is

$$w^2 = \frac{(\mathbf{u}-\mathbf{v})^2 - (\mathbf{u}\times\mathbf{v})^2/c^2}{(1-\mathbf{u}\cdot\mathbf{v}/c^2)^2}. \tag{2.4.8}$$

The square of the relativity velocity, (2.4.8) is invariant under Möbius transforms (2.2.18) with $|\bar{a}| > |\bar{c}|$. If we replace the relative velocities by $\mathbf{u}'$ and $\mathbf{v}'$ relative to some other frame, the value of (2.4.8) will be unaffected by the change.

2.5 A Brief History of Hyperbolic Geometry

The elliptic plane can be developed on a sphere; the hyperbolic plane on a hyperboloid. It took almost two thousand years to appreciate that on such planes Euclid's fifth postulate would be violated.

Hyperbolic geometry was born in 1829 when Lobachevsky showed that in a right triangle with a fixed side d, as the opposite vertex P moves infinitely far away, the angle α increases to a limit $\alpha_0 = \Pi(d) < \pi/2$, as shown in Fig. 2.17.

If the unit of distance is properly chosen, Lobachevsky derived

$$d = -\ln\tan(\Pi(d)/2).$$

Some forty years later, Beltrami showed that this unit of distance corresponds to a surface negative curvature, -1.

The following year, Lobachevsky was already looking for applications of his 'imaginary' geometry. If the universe is indeed non-Euclidean, then the unit of distance must be much larger than our solar system. If the vertex is the star Sirius, and the distance d is that of the Earth's orbit, the parallax of Sirius would be $1.24''$.[b] The parallax of stars is the annual oscillation

Fig. 2.17. A right triangle in hyperbolic space: As P increases without limit the angle tends to the angle of parallelism which is a function only of d.

[b]Actually, the parallax of Sirius is $0.37''$.

of the star's apparent position due to the Earth's motion about the sun. It depends on the distance that the star is from the Earth. Bradley back in 1725 tried to measure the distance to a star using the diameter of the Earth's orbit as a baseline. He had hoped to determine stellar distances in much the same way that surveyors measure distances by triangulation. However, what he measured was not the parallax for it depended on the Earth's *motion*, and not its *position* at a given point in the orbit. We will return to the phenomenon he discovered, stellar aberration, in Sec. 10.1.

The parallax is measured by comparing the apparent position of a star S with that of some reference star S' which is much more distant. This is shown in Fig. 2.18, where the angle ϕ is the parallax of the star. It is the upper limit on the defect $\mathbb{D}$ of the triangle $\triangle ASM$,

$$\mathbb{D} = \pi - \left(\frac{\pi}{2} + \alpha + \beta\right) < \frac{\pi}{2} - \alpha = \phi.$$

Three years after Lobachevsky's first publication, J. Bolyai published his own version of hyperbolic geometry. As we saw in Sec. 1.2.1 Gauss, a friend of Bolyai senior, did nothing to encourage his son to develop his ideas further. Probably the reason can be found in Gauss's 1824 letter to Taurinus where he writes:

> I have sometimes in jest expressed the wish that Euclidean geometry is not true. For then we would have an absolute a priori unit of measurement.

Gauss never published anything during his lifetime on hyperbolic geometry, as it came to be known. We have also mentioned in the preface that

Fig. 2.18. The parallax of a star.

Riemann noted in his *Habilitation* that the metric of a manifold of constant curvature, α, could be written as:

$$ds = \frac{\sqrt{(dx_1^2 + \cdots + dx_n^2)}}{1 + \frac{\alpha}{4}(x_1^2 + \cdots + x_n^2)},$$

where $\alpha = +1, -1$ for elliptic and hyperbolic spaces, respectively.

The next advance came in 1868 with two publications by Beltrami [Stillwell 91]. The conclusion of his first paper was that two-dimensional non-Euclidean geometry is simply the study of surfaces of constant negative curvature. He coined the name 'pseudosphere' of radius R, for a bugle looking surface of negative constant curvature, $-1/R^2$. The pseudosphere is the surface of revolution that is obtained by revolving the tractrix about its axis of symmetry, as shown in Fig. 2.19. The pseudosphere has total curvature -2π, and when it is divided by its constant curvature, $-1/R^2$ gives, surprisingly, a finite area $2\pi R^2$.

A tractrix is the track that a dog on a leash of unit length leaves who is being pulled by his master walking along the x-axis. The curve is determined by the property that its tangent lines meet the x-axis at a unit distance from the point of tangency. The tractrix was known to Newton as far back as 1676, and the pseudosphere was investigated by Huygens as early as 1693. Huygens established that its surface area is finite, and found its volume and the enclosed center of mass of the solid are also finite.

After having read Riemann's 1854 inaugural address, which was only published posthumously in 1868, Beltrami realized, in his second paper,

Fig. 2.19. Tractrix and pseudosphere as its surface of revolution.

that the points of an n-dimensional non-Euclidean geometry are identical to the interior points of a hemisphere:

$$y = \sqrt{(c^2 - x_1^2 - \cdots - x_n^2)}, \quad y \geq 0,$$

in an $(n+1)$-dimensional Euclidean space, and provided it with the Riemann metric,

$$ds = R\frac{\sqrt{(dx_1^2 + \cdots + dx_n^2 + dy^2)}}{y}. \tag{2.5.1}$$

The metric (2.5.1) is an obvious generalization of (2.1.1) to give it $n-1$ more dimensions. So it was Beltrami who actually discovered the Poincaré disc model some 14 years before he did!

Beltrami also appreciated that the boundary points at $y = 0$ are infinitely far from the interior of this metric. These points are the coldest regions of the heated plane model, and are referred to as points at infinity in the projective plane.

Projecting the hemisphere stereographically onto the disc,

$$x_1^2 + \cdots + x_n^2 \leq c^2,$$

Beltrami obtained the *conformal* disc model with metric,

$$ds = \frac{\sqrt{(dz_1^2 + \cdots + dz_n^2)}}{1 - \frac{1}{4R^2}(z_1^2 + \cdots + z_n^2)},$$

which had already been obtained by Riemann. Then, performing an inversion in a boundary point of the disc, Beltrami obtained the half-plane model, with coordinates $x_1, \ldots, x_n$ and $y \geq 0$ whose metric is given by (2.5.1). Beltrami gave credit to Liouville for having written down the two-dimensional case earlier, precisely the credit that was denied to him in having discovered the half-plane model in the n-dimensional case!

The two-dimensional formula, (2.1.1), was derived by Liouville in 1850 by mapping the pseudosphere into the half-plane, but he did not realize that the half-plane with his distance formula was a model of hyperbolic geometry. Twenty-one years were to pass before Klein formulated Beltrami's projective disc model in the language of projective geometry. A sphere in elliptic geometry with radius R has constant positive curvature, $1/R^2$. A sphere in hyperbolic space also has constant curvature, but it

is negative, $-1/R^2$. Therefore, if an elliptic space has radius R, its hyperbolic counterpart has radius iR.

To construct an n-dimensional sphere we begin with the equation of a circle,

$$c^2 = x_0^2 + x_1^2 + \cdots + x_n^2,$$

to which we have added an extra dimension. This gives rise to a Euclidean metric $ds^2 = dx_0^2 + dx_1^2 + \cdots + dx_n^2$. Constraining this metric to the unit sphere, $c = 1$, gives a Riemannian metric of constant positive curvature, $+1$.

Alternatively, if we begin with the indefinite metric,

$$ds^2 = -dx_0^2 + dx_1^2 + \cdots + dx_n^2, \tag{2.5.2}$$

which is associated with a hyperbola, $c^2 = -x_0^2 + x_1^2 + \cdots + x_n^2$, and then a sphere of radius i centered at the origin is the hyperboloid, $c^2 = -1$. A hyperboloid is the surface of revolution obtained by rotating the hyperbola around x_0. We pause for a moment to relate (2.5.2) to space-time.

Consider two inertial frames, S and S', both traveling at the same uniform speed but in opposite directions. The space-time coordinates of one frame, x, t, must be linear functions of the other frame, x', t', viz.

$$x = Ax' + Bt',$$
$$x' = Ax - Bt.$$

If we place ourselves at the origin of S, we measure a velocity $B/A = -u$ in S'. Likewise, if we are at the origin of S', we measure a velocity $B/A = u$ in S.

Now, we consider the propagation of light signals in both frames; in S we have $x = ct$, while in S', $x' = ct'$. When these equations are introduced into the above pair of linear equations, we get

$$t = (A + B/c)t',$$
$$t' = (A - B/c)t.$$

The times can be eliminated from these equations to get a condition on the constants, i.e.

$$c^2 = A^2(c^2 - u^2),$$

where we used $B/A = u$. Rearranging we find

$$A = \frac{1}{\sqrt{(1 - u^2/c^2)}} =: \gamma.$$

Thus, the Lorentz transformation is

$$x' = \gamma(x - ut), \quad ct' = \gamma(ct - ux/c). \tag{2.5.3}$$

Now squaring both sides of the first equation, and subtracting it from the square of the second give:

$$x'^2 - c^2t'^2 = x^2 - c^2t^2.$$

We may now identify x_0 with ct in (2.5.2). The Lorentz transformation thus consists in passing from one set to another set comprised of a time-like semi-diameter $ct = 1$, and a space-like semi-diameter $x = 1$ of the hyperboloid,

$$x^2 + y^2 + z^2 - (ct)^2 = -1, \tag{2.5.4}$$

and taking the lengths of the new semi-diameters for time and space coordinates.

Actually, Minkowski wrote the Lorentz transform (2.5.3) in the form:

$$x' = x\cos\omega + (ct)\sin\omega, \quad y' = y, \ z' = z,$$
$$ct' = -x\sin\omega + (ct)\cos\omega,$$

and concluded that the Lorentz transformation may be described as

> a rotation in a four-dimensional space x, y, z, ct, through an imaginary angle ω in the plane x, ct, or 'round the plane' y, z.

Minkowski took seriously his pseudo-Euclidean space for he wrote in his 1909 "Time and space" paper:

> The world postulate permits identical treatment of the four coordinates x, y, z, t. By this means, as I shall now show, the forms in which the laws of physics are displayed again in intelligibility. In particular the idea of acceleration acquires a clear-cut character.
>
> I will use a geometrical manner of expression, which suggests itself at once if we tacitly disregard z in the triplet x, y, z. I take any world-point O as the zero-point space-time. The cone $(ct)^2 - x^2 - y^2 = 0$ with apex O in Fig. 2.20 consists of two parts, one with values $t < 0$, the other with values $t > 0$. The former, the front cone of O consists, let us say, of all the world-points which "send light to O," the latter, the back cone of O, of all the world-points which "receive light from O." The

Fig. 2.20. Minkowski's vision of space-time.

territory bounded by the front cone alone, we call "before" O, which is bounded by the back cone alone, "after" O. The hyperboloid sheet already discussed [(2.5.4)] lies after O. The territory between the cones is filled by the one-sheeted hyperboloid figures

$$x^2 + y^2 + z^2 - (ct)^2 = k^2$$

for all constant positive k. We are specially interested in the hyperbolas with O as center, lying on the latter figures. The single branches of these hyperbolas may be called briefly the internal hyperbolas with center O. One of these branches, regarded as a world-line, would represent a motion which, for $t = -\infty$ and $t = \infty$, rises asymptotically to the velocity of light, c.

Minkowski's view of space-time has been reproduced in almost every book written on the special theory of relativity. It has led to many speculative thought-experiments regarding communication and space travel. Yet, *it lies outside the domain of the hyperbolic plane, and it is in this plane where all the physics occurs*, including the velocity addition law which stands in the defense of Poincaré's (Einstein's) postulate that c be the limiting velocity.

In order to get a projective space we have to identify antipodal points. These points lie on disjoint sheets of the hyperbola, the north N and S poles. Just as we have different types of maps which represent the surface of the Earth, different maps can be used to represent the hyperbolic plane.

But, in order to fully understand what Beltrami did let us consider the projection of the sphere onto a plane. The map from the hemisphere onto a plane is called a geodetic projection. A sphere is centered at the origin and has a radius r. A map from a horizontal plane at height κ to the hemisphere is given by the projection along the radius by the magnification $(u, v, w) \mapsto (\lambda u, \lambda v, \lambda r)$ such that $(\lambda u)^2 + (\lambda v)^2 + (\lambda r)^2 = \kappa^2$. Solving for the magnification

Fig. 2.20 → Minkowski´s vision of space-time – interessante. Simular em curvatura.

yields [cf. (2.2.11) above]

$$\lambda = \frac{\kappa}{\sqrt{(r^2 + u^2 + v^2)}}.$$

The distance between (u, v) and $(u + du, v + dv)$ is given by the first fundamental form

$$\begin{aligned} dw^2 &= E^2\, du^2 + 2F\, du\, dv + G\, dv^2 \\ &= \kappa^2 \frac{(r^2 + v^2)du^2 + 2uv\, du\, dv + (r^2 + u^2)dv^2}{(r^2 + u^2 + v^2)^2}. \end{aligned}$$

The absolute constant, κ, is related to the constant positive curvature, i.e. $1/\kappa^2$.

To see the effect on how distances become distorted, just set $v = 0$,

$$dw = \kappa \frac{r\, du}{r^2 + u^2}.$$

In order to get the same increments in dw, we have to consider larger and larger increments in du, as depicted in Fig. 2.7. This is to say that viewed by us Euclideans, it appears that our rulers become longer and longer the farther we travel from the origin.

In contrast, Beltrami considered the projection of a pseudosphere onto a horizontal plane by changing the surface to one of constant negative curvature, $-1/\kappa^2$. Beltrami called the surface of constant negative curvature a 'pseudosphere,' changing the name Minding had given his surface, Fig. 2.19.

The pseudosphere, as we have mentioned earlier, possesses some remarkable properties. Many geodesics can be drawn through a point on the surface of the pseudosphere that never meet a given geodesic. If three angles of one triangle are equal respectively to three angles of another, the triangles have equal areas. This is true also in elliptic geometry, and shows that in non-Euclidean geometries, the angles determine the sides of a triangle, something that is not true in Euclidean geometry. In other words, the size of a triangle cannot be altered without distorting it.

Beltrami writes in his *Saggio* that

$$dw^2 = \kappa^2 \frac{(r^2 - v^2)du^2 + 2uv\, du\, dv + (r^2 - u^2)dv^2}{(r^2 - u^2 - v^2)^2} \tag{2.5.5}$$

represents the square of a line element on a surface whose spherical curvature is constant, negative, and equal to $[-1/\kappa^2]$. The form of this expression ... has the particular advantage (from our point of view) that a linear equation in u, v represents a geodesic and, conversely, any geodesic is representable by a linear equation in these variables.

In order to derive (2.5.5), Beltrami considered the map from a horizontal plane of height r to the hyperboloid H^+ given by the projection $(u, v, w) \mapsto (\lambda u, \lambda v, \lambda w)$, where $w = r$ to the hyperboloid $(\lambda r)^2 - (\lambda u)^2 - (\lambda v)^3 = \kappa^2$. To see what distortion there is, we again set $v = 0$,

$$dw = \kappa \frac{r\,du}{r^2 - u^2}.$$

Now equal increments in dw require smaller and smaller increments in du as we move away from the origin. In other words, our rulers become smaller and smaller as they approach the rim of the disc so that it would appear that the rim is infinitely far away.

Beltrami achieved this without producing a surface in three-dimensional Euclidean space that would be analogous to a hemisphere, for no such surface exists. The pseudosphere cannot be considered such a surface since it has a discontinuity where geodesics cannot tread. Klein, however, did indicate how a pseudosphere could be drawn on Beltrami's disc. Cut it open and place the cusp end on the rim of the disc. The above metric tells us that the rim of the disc is infinitely far away.

Now, what Beltrami did was to project stereographically the upper hyperboloid sheet, H^+, onto the unit disc so that all the rays would converge at the origin, O, as shown in Fig. 2.21. In this way Klein got the projective model, which now bears his name , of rays falling onto the horizontal plane $z_0 = \text{const}$.

Somewhat earlier, Weierstrass introduced coordinates, analogous to spherical coordinates, to describe a sphere of imaginary radius. Since the radial coordinate is imaginary it is not difficult to see that the appropriate coordinates are

$$x = \kappa \sinh(r/\kappa)\cos\varphi, \quad y = \kappa \sinh(r/\kappa)\sin\varphi, \quad z = \kappa \cosh(r/\kappa),$$

where κ is the absolute constant that sets the scale. If we square the third term and subtract the squares of the other two terms we get

$$z^2 - x^2 - y^2 = \kappa^2,$$

Fig. 2.21. Projection of the hyperboloid onto the plane.

which is none other than our hyperboloid with $z = ct$. The semi-diameter κ sets the scale and is often set equal to unity for mere convenience.

On his surface of constant negative curvature, $-1/\kappa^2$, Beltrami used the Weierstrass coordinates in the form of ratios. That is, there is a map from the upper half-hyperboloid, H^+, to any disc with its center on the z-axis parallel to the xy-plane. A convenient choice has the disc touching the upper hyperboloid at its lowest point $z = 1$. The map sends the coordinates,

$$(a \sinh(r/\kappa) \cos\varphi, a \sinh(r/\kappa) \sin\varphi, a \cosh(r/\kappa)),$$

into the homogeneous coordinates $(u, v, 1)$, where

$$u = a \tanh(r/\kappa) \cos\varphi, \quad v = a \tanh(r/\kappa) \sin\varphi, \tag{2.5.6}$$

are rectilinear coordinates.

Projective geometry allows points of infinity, such as those where parallel train tracks merge in a drawing, to be placed on the same level as any other coordinates in $(X, Y) \in \mathbb{R}^2$. The so-called *homogeneous* coordinates were introduced by Möbius and Plucker in the early part of the nineteenth century. By extending the coordinates to all real triples, (x, y, z), and dividing through by z to obtain $(x/z, y/z, 1)$, these triples are just the coordinates

of a line in $\mathbb{R}^3$ from 0 to (X, Y), where $X = x/z$ and $Y = y/z$ are the homogeneous coordinates. All horizontal lines whose points have coordinates $(x, y, 0)$ corresponds to points at infinity. Thus, the extra coordinate z enables us to create new points, and, in particular, the points at infinity. As $z \to 0$, both X and Y tend to infinity, so it is entirely reasonable to consider them as 'points at infinity.'

If Weierstrass's coordinates are interpreted as the space-time coordinates in a two-dimensional space then Beltrami's coordinates are the velocity coordinates of the fundamental disc. In Beltrami's own words:

> If we denote by the letters x and y the rectangular coordinates of points of an auxiliary plane, then the equations
>
> $$x = u, \quad y = v$$
>
> determine a representation of the region under investigation in which to every point of the region there corresponds a uniquely determined point of the plane and *vice versa*; and the whole region turns out to be represented in the interior of a circle of radius $[c]$ with center at the origin that we will call the *limit circle*. In this representation the chords of the limit circle correspond to the geodesics of the surface and, in particular, the parallels to the coordinate axes correspond to the coordinate geodesic lines.

In fact, Beltrami's coordinates,

$$u = c \tanh(r/\kappa) \cos\varphi, \quad v = c \tanh(r/\kappa) \sin\varphi,$$

satisfy

$$u^2 + v^2 = c^2 \tanh^2(r/\kappa) < c^2.$$

Taking the square root and inverting we have

$$r = \kappa \tanh^{-1}\left(\frac{\sqrt{(u^2+v^2)}}{c}\right) = \frac{\kappa}{2} \ln\left(\frac{c + \sqrt{(u^2+v^2)}}{c - \sqrt{(u^2+v^2)}}\right).$$

The argument of the logarithm is none other than the cross-ratio $\{0, r|c, -c\}$, where $r = \sqrt{(u^2 + v^2)}$ is the distance from the center of the disc to a given point. Hence, r is the distance between any two arbitrary points in Beltrami's model; and the whole sphere of imaginary radius, or hyperboloid, is represented by the interior of the circle of radius c, the speed of light *in vacuo*.

Fig. 2.22. Geodesics determined by planes cutting the hyperboloid and passing through the center.

Geodesics on the hyperboloid are described by planes that pass through a given point p in the direction of the tangent vector to the hyperboloid and pass through the origin. This is shown in Fig. 2.22. The projection onto the unit disc makes them straight lines, which is what we normally expect of geodesics. But, there is a price to pay, namely, angles become distorted and the model is not conformal.

So *if we restrict ourselves to the disc, where hyperbolic geometry rules, we cannot reason in terms of space-time, but, rather, in terms of their ratios, the velocities*. The distance we want is the distance between two relative velocities. And although Beltrami provided the first proof of the consistency of Lobachevsky's plane geometry by representing it in the Euclidean plane, he gave no formula for the distance between two arbitrary points. Klein began with Cayley's expression for the non-Euclidean measure of distance,

$$\frac{1}{2}\ln\frac{e(ap)}{e(aq)}\cdot\frac{e(bq)}{e(bp)} > 0, \tag{2.5.7}$$

which we recognize as one-half the natural logarithm of the cross-ratio, $\{p, q|a, b\}$ between two interior points p and q, and two boundary points a and b, as shown in Fig. 2.23.

One-half is introduced so that the curvature will be -1, and $e(aq)$ is the Euclidean distance from a to q. The factor of one-half is very important

Fig. 2.23. Cayley's calculation of distance in the projective disc model.

since it is then distinguished from the Poincaré half-plane model in which the one-half is not present [cf. Chapter 10]. For Poincaré's model will turn out to be conformal, whereas Klein's is not. In the same paper Klein [71] also coined the term 'hyperbolic geometry' as the non-Euclidean geometry of Lobachevsky and Bolyai.

Another model of the hyperbolic plane is to stereographically project from the south pole, S, of the lower hyperboloid sheet, H^-, onto the upper hyperboloid sheet, H^+. The stereographic projection of these rays located on the unit disc in the horizontal plane $x_0 = 0$, shown in Fig. 2.24, has come to be known as the Poincaré disc model.

There are many proofs that non-Euclidean geometries are consistent. The earliest one was given by Beltrami who represented non-Euclidean geometries on Euclidean surfaces of constant curvature. Beltrami's favorite was the hemisphere, and he used it to go from his flat model to the Poincaré model of the hyperbolic plane in two maps. In view of the facts that he did this in 1868, and that Poincaré did not get around to doing this till 1882, this model should also be attributed to Beltrami. This is a classic example of Stigler's law of eponymy, which states that no scientific discovery is named after its rightful discoverer.

The maps from the Beltrami flat plane model to the Poincaré model consist of the following. Beltrami's model is located in the disc B of radius r in (a) of Fig. 2.25. A sphere of the same radius is placed over the disc with its south pole at the center of B in (b). Using vertical parallel — and not stereographic — projection, B will be projected onto the southern hemisphere with the disc radius coinciding with the equator, as shown in (c) of Fig. 2.25. From the north pole, the southern hemisphere is, this time,

Fig. 2.24. The Poincaré disc model as a stereographic projection from the south pole S of the bottom sheet.

stereographically projected back onto the plane, which covers a circular region P of radius r' in (d). This is the Poincaré disc.

The straight lines of the Beltrami model undergo a transformation under these maps. Under the first map, a chord of B rises to the sphere to become an arc of a circle which intersects the equator at right angles in (e) of Fig. 2.25. Under the second map this arc is mapped back into a circular arc that cuts the boundary of P normally in (f). As a consequence of these two maps, one is a vertical parallel projection and the other a stereographic projection, the hyperbolic straight lines are transformed into circular arcs that cut P at right angles. Although we lose the characterization of geodesics as straight lines, we still preserve the angles: Euclidean and hyperbolic angles are equal so the model is conformal. The two mappings are summarized in Fig. 2.26.

Fig. 2.24 → Poincaré disk model apresenta inconsistências, pois este gráfico está representado de forma equivocada. O correto é o meu modelo – M.U.S.

Fig. 2.25. Beltrami's double mapping of Klein and his hyperbolic disc model onto the Poincaré disc model.

Fig. 2.26. The combined vertical orthogonal projection upwards and the stereographic projection downwards.

So who exactly did what, and who should get the credit: is it Beltrami or Klein? Beltrami's approach was to show that hyperbolic geometry is consistent if Euclidean geometry is. Klein, on the other hand, worked from projective geometry and showed that all three geometries, elliptic, hyperbolic, and Euclidean, are consistent if projective geometry is consistent. And projective geometry comes before Euclidean geometry. To Beltrami the hyperbolic plane lies in a portion of the Euclidean plane, the unit disc. Outside the disc there is nothing. But to Klein, who believed in points at infinity, the plane is the projective, and not the Euclidean, plane. So Klein was able to go beyond the boundary of the disc and showed how distinct forms of rotation could take place within the disc, on the rim of the disc, and outside of the disc. Today, these differences seem marginal since the foundation for all geometries are based on real number theory, where points are n-tuples and planes are the equations they satisfy [Stillwell 91].

In 1882 Poincaré studied the Liouville–Beltrami upper half-plane model in regard to fractional linear transformations of a complex variable. Poincaré showed that the cross-ratio of two points, z and $z + dz$, infinitesimally separated on the same geodesic semi-circle with endpoints lying on the x-axis that could be written as $1 + |dz|/y$, when higher than linear-order infinitesimals are ignored. The distance is the logarithm of the cross-ratio, which in this case is

$$\ln(1 + |dz|/y) = |dz|/y, \tag{2.5.8}$$

to linear-order in the infinitesimal. This connects the geometry of the half-plane, or our heated plane, with the Poincaré metric $|dz|/y$ to the cross-ratio whose logarithm is the distance between any two points in the interior of the unit disc.

By mapping the upper half-plane onto the unit disc, Poincaré again obtained the representation of the hyperbolic plane in the interior of a circle. At the expense of having hyperbolic straight lines, or geodesics, they now appear as arcs of circles that cut the unit disc orthogonally. This may appear as a blemish, but the model is conformal: Euclidean and hyperbolic measures of an angle are the same. Let A and B be points inside the unit disc and let P and Q be the points where the line intersects the disc, as shown in Fig. 2.27.

Fig. 2.27. Geodesics consist of arcs that cut the disc, Ω, orthogonally.

Then, Poincaré defined the cross-ratio in the usual way,

$$\{A, B|P, Q\} = \frac{e(AP)}{e(AQ)} \cdot \frac{e(BQ)}{e(BQ)},$$

where $e(AP)$ is the Euclidean length of AP. But, unlike Cayley, Poincaré defined his length $d(AB)$ as

$$d(AB) = |\ln\{A, B|P, Q\}|,$$

which is precisely *twice* that of Cayley's.

Poincaré also studied motions and considered the group of all fractional linear transformations of the form

$$z \mapsto \frac{az + b}{cz + d}, \tag{2.5.9}$$

which we recognize as Möbius transformations. Poincaré worked with real coefficients, a, b, c, d and the determinant, $\Delta > 1$. Poincaré found in (2.5.9) a new type of periodic function that is invariant under this substitution. Up until this time the only periodic functions that were known were the trigonometric and elliptic functions. The double periodicity of the elliptic functions could be characterized by a tessellation of the Euclidean plane in which the elliptic functions take on the same value at the vertices of parallelograms.

As we have seen in Sec. 1.2.2, tessellations consist of curvilinear triangles inside the disc in the hyperbolic plane, as depicted in Fig. 1.1. As mentioned there, the tessellation was originally constructed by H. A. Schwarz in 1872 to explain the periodicities in the solutions of Gauss's differential equation. In the passage quoted there, Poincaré had the wonderful idea

that these new fractional transformations, (2.5.9), could be used to define a new distance for which the tessellations all become of equal size. His fractional transformation maps the upper half-plane model onto itself if $\Delta > 0$, which excludes the lower half-plane. We know from (2.1.7) that (2.5.9) can be decomposed into a magnification, translation, and inversion. Each of these preserves the metric (2.5.8), and so do (2.5.9).

Poincaré's measure of distance was twice as great as Cayley (2.5.7), and as we have mentioned, it preserves angles and so is conformal. Two Poincaré lines are parallel if and only if they have no point in common. An example is two arcs of a circle that cut the unit circle which do not intersect. This permits all the axioms of hyperbolic geometry to be translated into Euclidean-geometrical statements. Thus, the Poincaré model gives still further proof that if Euclidean geometry is consistent so too is hyperbolic geometry.

In the following year, Poincaré studied the motions consisting of all fractional linear transformations of the plane of points at infinity by allowing the coefficients in (2.5.9) to become complex, $z \mapsto e^{i\theta}z$. Poincaré also introduced the half-space and hemisphere models, which we have discussed in the example of the heated plane. They can be considered as 'first cousins' of the disc model because they can be derived from one another by inversions [Thurston 97].

They can also be derived from one another by the linear fractional transformation,

$$z \mapsto \frac{1 - zi}{z - i}.$$

To see this [Stahl 08], consider a point, $z = x + iy$ on the interior of the unit disc, and another point $w = u + iv$ in the upper half-plane. Then

$$w = \frac{1 - zi}{z - i},$$

is translated into

$$u + iv = \frac{1 - (x + iy)i}{x + iy - i}.$$

Separating real and imaginary terms, differentiating, and using the Cauchy–Riemann relations, we find that if there is a curve γ in the unit

disc model then there will be another curve, Γ in the upper half-plane such that

$$\int_\Gamma \frac{\sqrt{(du^2 + dv^2)}}{v} = \int_\gamma \frac{2\sqrt{(dx^2 + dy^2)}}{1 - x^2 - y^2}.$$

This relates the heated plane metric to the unit disc metric, which was first written down by Riemann.

The geometric interpretation of all fractional linear transformations of the form (2.5.9) as length-preserving, or isometries of the hyperbolic plane, is just not possible because of the infinite number of them. Poincaré's idea was to decompose the linear fractional transformations into individual motions and to express them as products of inversions. But what he failed to notice was the one with $a = d$ and $b = c$, such that $b/a = \tanh\psi = z_1$ is an inner point of the unit circle. For then

$$z' \mapsto \frac{z + z_1}{1 + zz_1}, \tag{2.5.10}$$

which maps the unit circle onto itself sending z_1 into 0. And for $z = z_1$, (2.5.10) becomes the isomorphism that takes us from the Poincaré to the Klein, or projective, model. With the relative velocity given by $b/a = \tanh\psi$, (2.5.9) preserves the unit circle $z\bar{z} = 1$, which expresses Lorentz invariance, and the identification of (2.5.10) as the Poincaré composition law for relativistic velocities, that is usually attributed to Einstein. He would then not have needed to introduce his second postulate for it would be already incorporated in the statement that all transformations of (2.5.9), with the above definitions of the coefficients, leave the real unit circle invariant, and all interior points have velocities less than the speed of light.

Poincaré would have been able to study them by studying tessellations, which would be curvilinear triangles that make up right-angled polyhedra in relativistic velocity space, referred to as honeycombs [Coxeter 99]. The tessellations do not have the same size but are mapped onto themselves by the Lorentz transform. And since Möbius transforms preserve the cross-ratio, they can be used, according to Poincaré's wonderful idea, to define a new concept of length under which the cells of the tessellation are all equal. The geometry to which it gives rise to is hyperbolic geometry, and it is this geometry that is used by Poincarites. *A fortiori*, if some of the Poincarites lived in the half-plane and others in the unit disc, and

they could communicate between themselves, there would nothing that they could do or measure to tell their worlds apart. Only to us Euclideans would differences in their two worlds become noticeable. This is the origin of all relativistic effects. In this the cross-ratio has a fundamental role. And since the cross-ratio is none other than a product of longitudinal Doppler shifts, we must look to the Doppler shift for the origin of all relativistic phenomena.

The story of hyperbolic geometry does not end here, but for us it does. New advances involve the definition of a global manifold, for which remained no satisfactory definition throughout the nineteenth century. A chronological account of all later developments can be found in Milnor [82].

Chapter 7

General Relativity in a Non-Euclidean Geometrical Setting

As an older friend I must advise against it... In the first place you won't succeed; and even if you succeed, no one will believe you.
Planck's advise to Einstein against trying to formulate a general theory of relativity.

7.1 Centrifugal versus Gravitational Forces

General relativity is based on the notion that gravity, rather than being a force acting between masses, is the curvature of space-time itself. The source of the (positive) curvature is mass itself, just like electric charge is the source of the electromagnetic field. And just as free particles follow straight lines in space-time, they follow geodesics in the curved space-time of a gravitational field.

Calculations of the gravitational redshift, the time-delay of radar echoes from planets, the bending of light near a massive object, and the geodesic effect all offer their support to general relativity. Not very rarely can new insights be gained by looking at old, established results from a new point of view. The old quantum theory of the hydrogen atom, which combined a mixture of continuous and discrete conditions, was subsequently reinterpreted by wave mechanics. And wave mechanics was found to be able to go way beyond the hydrogen atom in explaining the atomic constitution of matter. It was the transition from particle to wave–particle duality that opened up our ability to explore the world of atoms.

So too the addition of the wave nature to the study of gravitation will allow us to explain the well-known relativistic effects of the time-delay in radar sounding, the deflection of light and the advance of the perihelion of Mercury. All this can be accomplished by widening our mechanical view

by allowing for the occurrence of optico-gravitational phenomena. And will we not need the entire optical spectrum for all the tests of general relativity fall within the short-wavelength limit.

No recourse to general relativity is necessary. And since these effects are static, no assumption need be made as to how gravitational interactions propagate with the exception of the gravitational redshift that does not use the spatial components of the metric. The trajectory of a light ray will be determined in the same way as in an inhomogeneous refractive medium. Fermat's principle of least time, in Sec. 2.2.3, relates the length and orientation of a light ray to the time for light to propagate along a path of the ray. The analogy between the index of refraction and the square root of twice the difference between the total and potential energies is also well-known from the quantum mechanical explanation of tunneling. It is precisely this separation of the metric and mechanical properties that are described by the potential energy that can be used to distinguish between the centrifugal and gravitational fields which cause acceleration. We shall return to this lack of equivalence of between gravitational and centrifugal forces which cause acceleration in Chapter 9, but we already have seen it in action in Sec. 2.2.3 where Maxwell used this strategy in his classic treatment of inversion in elliptic space.

If we take a flat space metric in the plane and consider a constant index of refraction, we will demonstrate that Fermat's principle is capable of yielding the phase of the oscillation of a Bessel function of the first kind in the periodic domain in the asymptotic short-wavelength limit. This is identical to the WKB result, and it allows us to associate a wave phenomenon with a geodesic trajectory. The only potential present is the repulsive centrifugal potential, and that keeps the trajectory open.

In contrast to the generalization of special relativity, where gravity is considered to be the curvature of space-time instead of a *bona fide* force, the centrifugal force is built into the phase of the Bessel function in the periodic domain where the trajectory consists of straight-line segments that are tangent to a caustic circle, whose radius is determined by the magnitude of the angular momentum, and the arc segment joining the points of tangency. Whereas all forces causing acceleration are on the same footing in general relativity, it is the gravitational force — and not the centrifugal

force — that has to be introduced by allowing for a variable index of refraction, implying that the medium through which the light ray propagates is inhomogeneous. In other words, the effect of gravitation is to make the medium optically denser in the neighborhood of a massive body, while the centrifugal force has no effect upon the optical properties of the medium.

Centrifugal, Coriolis and gravitational forces are usually considered to be fictitious insofar as they can be eliminated by a change of frame. The centrifugal and Coriolis forces can be transformed away by transforming to a non-rotating frame, while the fictitious force of gravity is transformed away by transforming from a non-free falling frame to a free-falling one. We can easily appreciate that the force of gravity will affect the optical properties of the medium while the centrifugal force affects the geometrical properties by determining the radius of the caustic circle separating bright and shadow regions.

All the well-known results of general relativity can be analyzed from this perspective. The presence of a Newtonian potential will cause the modification of the phase of the Bessel function and determine whether the orbit is periodic (bright zone) or aperiodic (shadow zone) depending on whether the total energy is negative or positive, respectively.

The bending of light requires a coupling of the gravitational and centripetal potentials that is commonly referred to as Schwarzschild's potential [cf. Fig. 7.6]. Here, it arises when we determine the extremum condition for Fermat's principle. It shows that like gravitational radiation, the interaction between a light ray and massive body is a quadrupole interaction without any appeal being made to general relativity.

In contrast, we shall find that the advance of the perihelion requires both the gravitational potential and the quadrupole interaction. In the general theory, the quadrupole interaction appears as a relativistic correction to the square of the transverse velocity in the conservation of energy. Whereas Newton's potential is the cause of the closed elliptical orbit, the quadrupole causes the perihelion to slowly rotate in a rosette orbit. A dipole moment would have been sufficient to cause the advance of the perihelion, but since there is conservation of momentum, the center of mass of the system cannot accelerate and so neither can the mass dipole moment.

Obs.: Coriolis and gravitational forces → estudar.

7.2 Gravitational Effects on the Propagation of Light

7.2.1 *From Doppler to gravitational shifts*

That motion causes changes in the frequency and/or wavelength has been known since the middle of the nineteenth century when J. C. Doppler discovered it. If the relative speed of the waves is not the same for a moving observer as for an observer at rest, there is a frequency shift even though the wavelength remains the same. Not so for light waves where the speed of light is the same for all observers, whether they be at rest or traveling nine-tenths the speed of light. The constancy of the speed of light imposes that both frequency and wavelength change such that their product, the speed of light remains c. The distinction between the two is that where frequency and wavelength change independently the vibrations belong to that of the medium but where they are negatively correlated the self-contained vibrations are of the electromagnetic fields, and not the media through which they propagate for there may even be none.

In Sec. 2.5 we have described how Einstein [11] considers c as the gravitational potential, thereby negating his principle of the constancy of the speed of light. Instead of inertial frames, he considers one frame to be uniformly accelerated with respect to the other. A light signal of frequency ν_0 is emitted from a source in a frame at rest. If light has traveled a distance h at a speed c then it will have acquired a speed gh/c which is the product of the (constant) gravitational acceleration, g, and the time, h/c. Thus, the first-order Doppler shift,

$$\nu = \nu_0 \left(1 + u/c\right),$$

is converted into

$$\nu = \nu_0 \left(1 + gh/c^2\right).$$

Now, on the strength of the equivalence principle, acceleration is equivalent to a gravitational field, and gh can be replaced by the gravitational potential, Φ, to get

$$\nu = \nu_0 \left(1 + \Phi/c^2\right), \tag{7.2.1}$$

or even,

$$c = c_0 \left(1 + GM/rc^2\right), \tag{7.2.2}$$

where c_0 is the velocity of light *in vacuo*. Einstein has made the following reduction:

relative motion $\longrightarrow$ uniform acceleration $\longrightarrow$ static gravitational field.

Thus, the speed of light is like the speed of water waves, it is different for stationary and moving observers, and even more, it depends on the position one is located in the gravitational field. From (7.2.2) Einstein deduces that a change in the velocity normal to a wavefront is proportional to the change in the gravitational potential. This makes c a potential for gravitation, and the latter is responsible for the change in the rate at which a clock ticks. What do the experiments say?

To get an effect on the change of rate of a clock on the gravitational field, one needs to consider a clock on Earth and another in a satellite orbiting the Earth. Comparison of the two clocks will require 'back-and-forth' light signals so in addition to the gravitational effect, (7.2.2), there will be the effect of time dilatation. A round the world trip was accepted as the second best substitute to satellite experiments, and in 1971 four atomic clocks were compared with a stationary observer after they had made round the world trips in eastward and westward directions.

The transported clocks feel a smaller gravitational attraction to the Earth than the grounded clock so that they will appear to go faster. The inertial system of the ground is that it moves with the Earth about the Sun but it does not partake in the Earth's rotation. Because gravity and time dilatation supposedly interfere destructively on the eastward journey the traveling clock should be slowed down, while, on the westward journey they complement one another so that there is a gain. The results were heralded as a great triumph for special relativity [Hafele & Keating 72].

Not only was the difference in time between the westward and eastward journeys of the same order as the difference between the individual clocks [Essen 78], but how does one go about decomposing time dilatation from gravitational effects? The latter certainly does not belong to the realm of special relativity.

7.2.2 *Shapiro effect via Fermat's principle*

We will now calculate the increased travel time of light in a gravitational field known as the Shapiro effect. We will not treat it from general relativity, nor by (7.2.2), but, rather, as an example of Fermat's principle of least time.

Fermat's principle asserts that the ray path connecting two arbitrary points makes the optical path length,

$$I = c\tau = \int \eta\sqrt{(2T)}\, dt, \tag{7.2.3}$$

stationary, where, as before, η is the index of refraction, c the velocity of light, τ, the propagation time, and T is the kinetic energy per unit mass.

As a first application of Fermat's principle (7.2.3) we will determine the time-delay in radar sounding. We will later see, in Sec. 9.10.3, how general relativity accounts for this time-delay by evaluating the Schwarzschild metric on the null geodesic when all the angular dependencies are ignored.

If a light signal is sent from Earth, located on the x-axis at $-x_E$, to Venus say, which is located behind the Sun at x_V, as shown in Fig. 7.1, the light ray will be bent as it passes the gravitational field of the Sun. Clocks will thus be slowed down, and the time it takes the ray to bounce off the surface of Venus and return to Earth will be longer than if the sun were not present.

The simplest mechanical analog of the index of refraction is $\eta = \sqrt{(1 - 4\Phi/c^2)}$, where Φ is the potential energy per unit mass. We will justify this choice shortly. Since the gravitational field of the Sun makes the medium optically denser, Φ can be identified as the gravitational potential, $-GM/r$, where G is Newton's gravitational constant, M the mass of the Sun, and $r = \sqrt{(R^2 + x^2)}$ is the distance from the center of the Sun to Venus, with R as the Sun's radius.

Fig. 7.1. The set-up for the Shapiro effect.

Now, according to Fermat's principle, (7.2.3), the propagation time τ along a ray connecting the two endpoints $-x_E$ and x_V is given by

$$\tau = \int_{-x_E}^{x_V} \frac{\eta(r)}{c} dx = \int_{-x_E}^{x_V} \frac{\sqrt{(1+2\alpha/r)}}{c}\, dx,$$

where $\alpha := 2GM/c^2$ is commonly referred to as the Schwarzschild radius. Every mass has its accompanying Schwarzschild radius: A human with a mass of 10^2 kg, and radius of 1 m has a Schwarzschild radius of 10^{-25} m, while the Sun with a mass of 2×10^{30} kg, and a radius of 7×10^8 m will have a Schwarzschild radius of 3×10^3 m.

The slowing down of clocks in a gravitational field will result in an apparent reduction in the speed of light. Light will therefore travel at the phase velocity $u(r) = c/\eta(r)$, rather than c as it does *in vacuo*.

> The gravitational potential enters through the index of refraction to modify the speed of light, and not through any putative connection with the Doppler effect.

Consequently, the travel time will be

$$\begin{aligned}\tau + \Delta\tau &\approx \tau_N + \frac{\alpha}{c}\int_{-x_E}^{x_V} \frac{dx}{r} \\ &= \tau_N + \frac{\alpha}{c}\int_{-x_E}^{x_V} \frac{dx}{\sqrt{(R^2+x^2)}},\end{aligned}$$

where $\tau_N = (x_E + x_V)/c$ is the Newtonian travel time, and we have used the approximation $\sqrt{(1+x)} \approx 1 + x/2$. The second term is half the time-delay for a signal to bounce off Venus and return to Earth.

Fermat's principle thus predicts a time dilatation,

$$\begin{aligned}2\Delta\tau &= \frac{2\alpha}{c}\ln\left(\frac{x_E + \sqrt{(R^2+x_E^2)}}{-x_V + \sqrt{(R^2+x_V^2)}}\right) \\ &\approx \frac{2\alpha}{c}\ln\left(\frac{4x_E x_V}{R^2}\right) = 2.4 \times 10^{-4}\,\text{s},\end{aligned}$$

where the square roots have been expanded to lowest order, $\sqrt{(R^2+x_E^2)} \approx x_E$ and $\sqrt{(R^2+x_V^2)} \approx x_V + R^2/2x_V$ since $R \ll x_V, x_E$. The factor 2 is due to the fact that the signal must make a round trip.

This is known as the Shapiro effect, and has been calculated without general relativity. The increased travel time corresponds to an apparent increase in distance of 36 km from Venus to Earth. In a simplified demonstration [Sexl & Sexl 79], the time-delay of radar due to the presence of a massive body is given by $\tau = \int dx/c_{\text{eff}}$, where the effective velocity of light is given by Einstein's expression (7.2.2), which supposedly accounts for both time dilatation and the shrinking of measuring rods in a gravitational field. The final expression for τ is valid to first-order in α/r. Both these factors have been incorporated into the stretching of the line element by the index of refraction $\eta = \sqrt{(1+\alpha/r)}$. Rather, if the effective velocity c_{eff} were to be identified with the phase velocity, there would be only half of the effect which is within 3% of the experimental uncertainty.

7.3 Optico-gravitational Phenomena

The wave equation for a wave of definite angular frequency ω may be written from (3.8.4) as

$$\nabla^2 \mathbf{A} + \frac{\omega^2}{c^2}\eta^2 \mathbf{A} = 0, \tag{7.3.1}$$

in terms of the vector potential intensity $\mathbf{A}$, or what Maxwell referred to as the 'electrokinetic momentum' intensity. This is the equation of light in a medium of index of refraction

$$\eta^2 = 2m\left[W - \Phi(r)\right]\frac{c^2}{\omega^2}, \tag{7.3.2}$$

where W is the total energy and Φ is the potential energy, which is supposed to be a function only of the radial coordinate r. The index of refraction is usually positive, but, under certain circumstances like the total internal reflection of light, it can be imaginary. In this case there is an exponential penetration of light from a denser to a less dense medium.

To see what this implies, take the scalar product of the subsidiary condition (3.8.9) with $\dot{\mathbf{J}}$; we then obtain

$$\frac{-\dot{\mathbf{J}} \cdot \nabla\rho}{\dot{\mathbf{J}}^2} = \frac{\eta^2}{c^2}.$$

Whereas in the normal case where the refractive index is real, the rate of change of the gravitation current is in the opposite direction to the density gradient, the case of an imaginary index of refraction would imply that the two are in the same direction.

Although (7.3.1) is what we have derived from the circuital equations, and the definition of the index of refraction, we will find that it is insufficient to account for relativistic gravitational phenomena. This is due to the fact that η accounts for the potentials, like the gravitational potential, $-GM/r$, but it cannot account for the metric dependent terms. This will become clear from Fermat's principle.

Expression (7.3.2) can be shown to agree with Cauchy's expression for the index of refraction — in this case Φ represents the gravitational potential. In 1836 Cauchy proposed a simple formula for the variation of the index of optical glasses with wavelength. Cauchy's formula depends only on two empirical constants, C_1 and C_2,

$$\eta = C_1 + C_2\omega^2. \tag{7.3.3}$$

For gases in which η differs little from unity, we can replace 2η by $\eta^2 + 1$, and write (7.3.3) as

$$\eta^2 = 2C_1 - 1 + 2C_2\omega^2. \tag{7.3.4}$$

Now consider (7.3.2) in the case where the density $\rho = 3M/4\pi r^3$ is constant. We then obtain

$$\eta^2 = -A + \frac{8\pi}{3}G\rho r^2, \tag{7.3.5}$$

where A is an arbitrary constant. But, $G\rho$ is proportional to the square of the frequency of free-fall so that we can write (7.3.5) as

$$\eta^2 = -A + B(\omega r)^2, \tag{7.3.6}$$

which is tantamount to Cauchy's formula, (7.3.4), where B is another arbitrary constant. Comparison of our original formula (7.3.2) with (7.3.6) embodies the equivalence relation,

$$\frac{GM}{r} = \omega^2 r^2. \tag{7.3.7}$$

In the remainder of this section we will use natural units where $G = c = 1$.

In the Euclidean plane where $\vartheta = \pi/2$, the kinetic energy, expressed in polar coordinates, is

$$2T = \dot{r}^2 + r^2\dot{\varphi}^2,$$

where φ is the azimuthal angle. However, we need not restrict ourselves to such a simple form of the kinetic energy. Rather, we can consider the expression

$$2T = E\dot{r}^2 + G\dot{\varphi}^2, \tag{7.3.8}$$

where E and G are the coefficients of the first fundamental form, which can be a function only of r.

Introducing (7.3.8) into (7.2.3) we get

$$\begin{aligned} I &= \int \eta \sqrt{\left(E\dot{r}^2 + G\dot{\varphi}^2\right)}\, dt \\ &= \int \eta \sqrt{\left(E + Gr^2\varphi'^2\right)}\, dr, \end{aligned} \tag{7.3.9}$$

where the prime indicates the derivative with respect to r. The true ray path connecting any two arbitrary points will make (7.3.9) stationary. Observing that φ is a cyclic coordinate in as much as it is not present in the integrand while its derivative with respect to r, φ', is; we know that a first integral to the motion exists. Calling the integrand Λ, it is

$$\frac{\partial \Lambda}{\partial \varphi'} = \frac{\eta G \varphi'}{\sqrt{\left(E + G\varphi'^2\right)}} = \ell,$$

which is a constant, regardless whether the medium is homogeneous or not. Recall that in an inhomogeneous medium, the refractive index will be a function of r. For the moment, we will assume, for simplicity, that it is a constant. The constant ℓ will be identified as the angular momentum in the natural units we are working in.

Solving for φ', we obtain the equation of the orbit as

$$\frac{d\varphi}{dr} = \frac{\dot{\varphi}}{\dot{r}} = \pm \frac{\ell\sqrt{E}}{\sqrt{G}\sqrt{\left(\eta^2 G - l^2\right)}}. \tag{7.3.10}$$

What we have derived in (7.3.10) is the famous Clairut parametrization, which is an orthogonal parametrization in which both parameters of the first fundamental form, E and G, are only functions of r. Solutions to (7.3.10)

are geodesics of constant speed and zero geodesic curvature. They are referred to as 'pre-geodesics,' and the geometrical interpretation of the angular momentum, ℓ, is the slant of the curve.

The geodesic equation (7.3.10) contains all the information we need. It may be decomposed into two equations: the definition of the angular momentum,

$$\ell = \frac{G}{\sqrt{E}}\dot{\varphi}, \tag{7.3.11}$$

and the radial equation,

$$\dot{r} = \pm\frac{\sqrt{(\eta^2 G - \ell^2)}}{\sqrt{G}}. \tag{7.3.12}$$

In Euclidean space $G = r^2$ and $E = 1$, (7.3.11) reduces to

$$\ell = r^2\dot{\varphi}, \tag{7.3.13}$$

which is Kepler's law of equal areas in equal times, while (7.3.12) determines two families of curves in the rt-plane — the so-called characteristic curves.

Instead of (7.3.1) we now have

$$\nabla^2\mathbf{A} + \left(\omega^2\eta^2 - \Omega\right)\mathbf{A} = 0, \tag{7.3.14}$$

where Ω is the centrifugal energy per unit mass,

$$2\Omega = \frac{\ell^2}{r^2}. \tag{7.3.15}$$

Although we have derived (7.3.14) as a geodesic from Fermat's principle, it would be instructive to look for its electromagnetic origin, which might shed some light on the appearance of the last term in (7.3.14).

Whereas (7.3.1) follows immediately from the circuital equations,

$$\begin{aligned} \nabla \times \mathbf{E} &= -\eta\dot{\mathbf{H}}, \\ \nabla \times \mathbf{H} &= \eta\dot{\mathbf{E}}. \end{aligned} \tag{7.3.16}$$

simply by introducing $\mathbf{H} = \nabla \times \mathbf{A}$, and the subsidiary equations,

$$\begin{aligned} \dot{\mathbf{E}} + \eta\ddot{\mathbf{A}} + \nabla\dot{\phi} &= 0, \\ \nabla \cdot \mathbf{A} + \eta\dot{\phi} &= 0, \end{aligned} \tag{7.3.17}$$

(7.3.14) needs an Ampère current,

$$\mathbf{J} = \Omega \mathbf{A}. \tag{7.3.18}$$

This converts the reduced wave equation,

$$\nabla(\nabla \cdot \mathbf{A}) + \omega^2 \eta^2 \mathbf{A} = \mathbf{J},$$

into (7.3.14). Equation (7.3.14) requires the divergence of (7.3.18) to vanish, which is not guaranteed solely by the vanishing of the divergence of the vector potential since Ω is a function of r. An auxiliary condition is needed that requires $\mathbf{r} \cdot \mathbf{A} = 0$, or that the vector potential be normal to the direction of propagation, which is the case of a transverse wave. A current proportional to the vector potential is a hallmark of superconductivity where the coefficient of the vector potential is proportional to the mass. We will return to this in Sec. 11.5.2.

In his studies of the transmission of electromagnetic waves along cylindrical cables, Heaviside [94] came across (7.3.14) with the centrifugal energy (7.3.15) in which the electric and magnetic fields were zero- and first-order Bessel functions when there was no angular variations. This necessitated considering two components of the electric field vector, **E** and **F**. Let us first consider the spherically symmetric case.

Let z be the axis of the cable of radius r_0, and r the distance from it. Then either **E** or **H** will be circular about this symmetry axis. In either case the electric field will have an additional, or radial, component **F**. If **H** is circular, and **E** longitudinal the circuital equations are

$$\frac{1}{r}\frac{\partial r H}{\partial r} = \epsilon \dot{E}, \quad -\frac{\partial H}{\partial z} = \epsilon \dot{F}, \quad \frac{\partial E}{\partial r} - \frac{\partial F}{\partial z} = \mu \dot{H}, \tag{7.3.19}$$

where $(1/r)(\partial/\partial r)r$ denotes the curl which operates on a solenoidal field. In contrast, $\partial/\partial r$ is the gradient, and it operates on an irrotational field. Differentiating the last equation in time and substituting in the first two equations lead to a Bessel equation for H whose solution is a Bessel function of order one,

$$H'' + \frac{1}{r}H' + \left(s^2 - \frac{1}{r^2}\right) H = 0,$$

where the prime stands for differentiation with respect to r, and

$$s^2 = \frac{\partial^2}{\partial z^2} - \eta^2 \frac{\partial^2}{\partial t^2},$$

while the equation for E is a Bessel function of order zero.

Rather, if H is longitudinal and E circular, the circuital equations are

$$\frac{\partial H}{\partial r} = \epsilon \dot{E}, \quad -\frac{\partial H}{\partial z} = \epsilon \dot{F}, \quad \frac{1}{r}\frac{\partial r E}{\partial r} - \frac{\partial F}{\partial z} = \mu \dot{H}.$$

Now, H satisfies

$$\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial H}{\partial r} + \frac{\partial^2 H}{\partial z^2} = \eta^2 \ddot{H}, \tag{7.3.20}$$

whose solution is a zero-order Bessel function, while E is a first-order Bessel function.

Finally, if both **E** and **H** are longitudinal, we get

$$\frac{\partial^2 H}{\partial r^2} + \frac{\partial^2 H}{\partial z^2} = \eta^2 \frac{\partial^2 H}{\partial t^2}. \tag{7.3.21}$$

Furthermore, if H has a periodic dependency on z, i.e. $e^{iz/\lambda}$, (7.3.21) becomes the Klein–Gordon equation when the wavelength λ is identified as the Compton wavelength. We will have much more to say about (7.3.21) in Sec. 9.5, but it should be borne in mind, even at this stage, that the Klein–Gordon equation involves only irrotational fields. Hence, Schrödinger's conclusion that

> Plane waves have only two possible states of polarization, not three, as would be expected for a vector wave (e.g. an elastic wave; remember the historical dilemma concerning the 'elastic properties of the aether').

As mass is associated with the longitudinal (helicity zero) state (cf. Sec. 9.6), we see that it is compatible with irrotational fields alone and does not arise from some spontaneous symmetry breaking in which the disappearance of a transverse degree of freedom makes its appearance as a longitudinal mode of vibration of the electromagnetic field.

Heaviside noted that when there are no angular variations the only Bessel functions are J_0 and J_1. Since the generalization to include angular dependencies, leading to higher-order Bessel functions is "so easily made

that it would be inexcusable to overlook it," we, along with Heaviside, consider it.

Take **H** longitudinal and the electric field with two components, one circular, E, and one radial component, F. The circuital equations are

$$-\frac{\partial H}{\partial r} = \epsilon \dot{E}, \quad \frac{\partial H}{\partial \vartheta} = \epsilon \dot{F}, \quad \frac{1}{r}\left(\frac{\partial rE}{\partial r} - \frac{\partial F}{\partial \vartheta}\right) = -\mu \dot{H}, \tag{7.3.22}$$

at $z = \text{const}$. Assuming H to be a periodic function of both angle and time, the resulting equation,

$$\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial H}{\partial r} + \left(\omega^2 \eta^2 - \frac{m^2}{r^2}\right) H = 0, \tag{7.3.23}$$

is Bessel's equation of order m.

By defining the analytic function $G = E + \mathrm{i}F$, we can write the circuit equations (7.3.22) as

$$\begin{aligned} \left(\frac{\partial}{\partial r} - \mathrm{i}\frac{\partial}{\partial \vartheta}\right) H &= -\epsilon \frac{\partial G}{\partial t}, \\ \frac{1}{r}\left(\frac{\partial}{\partial r} r + \mathrm{i}\frac{\partial}{\partial \vartheta}\right) G &= -\mu \frac{\partial H}{\partial t}. \end{aligned} \tag{7.3.24}$$

Differentiating the second equation in time gives

$$\frac{1}{r}\left(\frac{\partial}{\partial r} r + \mathrm{i}\frac{\partial}{\partial \vartheta}\right)\left(\frac{\partial}{\partial r} - \mathrm{i}\frac{\partial}{\partial \vartheta}\right) H = \eta^2 \ddot{H}.$$

Since we have considered all fields to be real, the real and imaginary parts of this equation must be equated to zero separately. The real part gives the equation for the Bessel function of order m, (7.3.23), while the imaginary part, when equated to zero,

$$-\frac{\partial E}{\partial \vartheta} = \frac{\partial r F}{\partial r},$$

is one of the Cauchy–Riemann conditions for the existence of an analytic function. This just says that the mixed second derivatives of G are equal.

Ironically, Heaviside loathed complex variables, going so far as to write to Bromwich "I could never stomach your complex integral method." Two years after Heaviside's death, Jeffreys was to show "that many of Heaviside's solutions could be obtained easily by workers without

his amazing skill in manipulation, by using the theory of the complex variable."

To understand the nature of the individual terms in (7.3.22) we may avail ourselves of Heaviside's construction of the power equation, or what he referred to as 'activity.' Again, Heaviside missed out on the discovery of the energy flux by a matter of months, and seeing that Poynting used Maxwell's original notation, it appears almost miraculously that he could have made the discovery. Heaviside's derivation was just two pages!

Multiplying the first, second and third equations in (7.3.22) by E, F and H, respectively, and combining them in such a manner that the following equation results

$$\frac{1}{r}\frac{\partial r\,EH}{\partial r} - \frac{1}{r}\frac{\partial FH}{\partial \vartheta} = -\frac{1}{2}\frac{\partial}{\partial t}\left\{\epsilon(E^2+F^2)+\mu H^2\right\}.$$

The right-hand side is just the decrease in the total energy due to the flow of energy toward the outside of the cylinder which is represented by the left-hand side. The total flow towards the outside, which is responsible for the subsequent decrease in energy, is obtained by multiplying both sides by $r\,dr\,d\vartheta$ integrating from $r=0$ to $r=r_0$ and from $\vartheta=0$ to $\vartheta=2\pi$. We then obtain

$$2\pi r_0 H(r_0)E(r_0) = -\int_0^{r_0}\int_0^{2\pi}\frac{d}{dt}\left\{\epsilon(E^2+F^2)+\mu H^2\right\} r\,d\vartheta\,dr, \qquad (7.3.25)$$

since the term in the derivative with respect to ϑ averages out to zero. The first term in (7.3.25) is the Poynting flux directed radially outward.[a] It involves only the circuital component of the electric field, and vanishes when r_0 is a zero of the Bessel function.

By contrast, in the case of the Klein–Gordon equation, (7.3.21), we would get an unphysical source term,

$$-2\pi\int_0^{r_0} EH\,dr,$$

from the necessity of performing an integration by parts. Hence, if the fields are entirely irrotational there will be no energy flux.

The case of spherical symmetry can be handled analogously, and in the presence of a gravitational potential it leads to the gravitational analog

[a]This agrees with Heaviside except for a minus sign.

of the nonrelativistic hydrogen atom. Again following Heaviside, the simplest spherical waves are those for which the lines of **H** are circles of equal latitude, centered on an axis from which the polar angle, ϑ, is measured. Here r is the distance from the origin, and the azimuthal angle will have no role in what follows. **H** is circuital while **E** will have two components: a circuital component, E, that coincides with a line of longitude, and a radial component F.

Heaviside writes down directly the wave equation for a spherical harmonic. However, it is of interest to see its origin in the circuital equations. The electric field, **E**, has two components: a radial component E, and a latitudinal circular component F. The magnetic field has but one component and is longitudinally circular. The circuital laws are thus

$$\mu\dot{H} = -\mathrm{curl}_\varphi \mathbf{E} = -\frac{1}{r}\left(\frac{\partial}{\partial r} rF - \frac{\partial E}{\partial \vartheta}\right), \qquad \text{[EM]}$$

$$\epsilon\dot{F} = \mathrm{curl}_\vartheta \mathbf{H} = -\frac{1}{r}\frac{\partial}{\partial r} rH,$$

$$\epsilon\dot{E} = \mathrm{curl}_r \mathbf{H} = \frac{1}{r\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta H.$$

The circuital equations [EM] can then be combined into a wave equation, or what Heaviside referred to as the 'characteristic' equation

$$\epsilon\mu\ddot{H} = \frac{1}{r}\frac{\partial^2}{\partial r^2} rH + \frac{1}{r^2}\frac{\partial}{\partial\vartheta}\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta H. \qquad (7.3.26)$$

The second term on the right-hand side of (7.3.26) just misses being the ϑ term in the Laplacian in spherical coordinates by the term $1/r^2\sin^2\vartheta$, viz.

$$\frac{\partial}{\partial\vartheta}\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta = \frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial}{\partial\vartheta}\right) - \frac{1}{\sin^2\vartheta}.$$

This term is analogous to the $m = \pm 1$ term for the magnetic quantum number of an electron. It represents the projection of the angular momentum on the preferred z-axis. For if we call

$$\lambda = \frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta\frac{\partial}{\partial\vartheta} + \frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2},$$

the 'surface harmonic,' $Y_\ell(\vartheta, \varphi)$ satisfies the differential equation

$$\Lambda Y_\ell + \lambda Y_\ell = 0, \tag{7.3.27}$$

where λ is an eigenvalue which we seek to determine.

Now Y_ℓ depends only on the angles, or equivalently the ratios x/r, y/r, and z/r, say to the power ℓ. We can thus consider an ℓ-th degree homogeneous function,

$$\Theta_\ell = r^\ell Y_\ell,$$

where Θ satisfies Laplace's equation, $\nabla^2 \Theta_\ell = 0$, which in spherical coordinates reads

$$\left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\right) r^\ell Y_\ell + \frac{\Lambda}{r^2} r^\ell Y_\ell = r^{\ell-2}\left[\Lambda + \ell(\ell+1)\right] Y_\ell = 0. \tag{7.3.28}$$

In view of (7.3.27) we find $\lambda = \ell(\ell+1)$. There are $2\ell+1$ values of m for each value of ℓ, and in this case $\ell = 1$ there should be three values, $m = 0, \pm 1$. The $m = 0$ is missing.

We can find the $m = 0$ value if we consider the propagation of the electric field. To find this equation we take the time-derivative of the third equation in [EM], introduce the first equation, and use the second and third equations to express the circular component of the electric field in terms of the radial component. We then obtain

$$\mu\epsilon \ddot{E} = \frac{1}{r}\frac{\partial^2}{\partial r^2} rE + \frac{1}{r^2 \sin\vartheta}\frac{\partial}{\partial \vartheta}\sin\vartheta \frac{\partial E}{\partial \vartheta}, \tag{7.3.29}$$

which has the correct form for the Laplacian in spherical coordinates with $m = 0$. In Sec. 11.5.2 we will show that (7.3.29) can support dispersion. There, we will also provide an interpretation for ℓ and m in terms of the properties of photons.

Returning to our main theme, and assuming a periodic time dependence, (7.3.26) reduces to

$$\left(\frac{d^2}{dr^2} - \frac{\ell(\ell+1)}{r^2} + \eta^2\omega^2\right) rH = 0, \tag{7.3.30}$$

which is Schrödinger's equation for the hydrogen atom. Moreover, since Coulomb's law has the same form as Newton's law, (7.3.30) can be solved

in the exact same way by replacing e^2 with GM in the expression for the index of refraction,

$$\eta^2 = \frac{2m}{\omega^2}[W - \Phi(r)] = \frac{2m}{\omega^2}\left(W + \frac{GM}{r}\right).$$

The square of the momentum is written to show that it has been derived from the square of the curl, and thus polarization has already been included in the solution to Schrödinger's equation without ever being realized. This is clear from the circuital equations [EM].

These equations describe the propagation of electromagnetic waves. For photons, the projection of the total angular momentum along the polar axis is replaced by the projection of its spin along the direction of motion. This is called *helicity*, and for a photon the helicity is either ± 1, but never zero. It is remarkable that this information is included in the classical circuital laws, as is made evident from (7.3.28). The absence of the helicity-0 state guarantees that a photon can never come to rest, i.e. it has zero rest mass.

Although we will return to problem of introducing a longitudinal mode in Sec. 11.5.5, we briefly indicate how this can be done. If $\mathbf{G}$ is a generalized displacement, the force acting on it will be made up of shear, compression, and rotation. The force per unit volume that arises from the stress of the medium which tends to oppose a finite elastic resistance to shear, compression and rotation is

$$\mathbf{F} = n[\nabla^2\mathbf{G} + \frac{1}{3}\nabla(\nabla\cdot\mathbf{G})] + \lambda\nabla(\nabla\cdot\mathbf{G}) - \mu\nabla\times\nabla\times\mathbf{G}, \qquad (7.3.31)$$

where the elastic constants related to shear, compression, and rotation are n, λ, and ν, respectively. The first term in (7.3.31) is the rigidity, and when there is frictional resistance, its time-derivative is the frictional resistance to distortion. We shall neglect such effects here and concentrate on the other two terms. The second term represents a uniform tension, and its negative represents the hydrostatic pressure. When the material is incompressible, λ becomes infinite, and $\nabla\cdot\mathbf{G} = 0$, but their product remains finite. The last term is the force that tends to rotate the body as a whole.

As we discussed in Sec. 3.8.1, there are times when it is more convenient to associate $\mathbf{H}$ to the velocity than $\mathbf{E}$. Yet, it was crucial to our derivation of the electromagnetic mass in Sec. 5.4.3 that we associate $\mathbf{H}$

with the velocity. Such will prove to be the case here. So with $\dot{\mathbf{G}} = \mathbf{H}$, and

$$\nu\nabla \times \mathbf{G} = \mathbf{E},$$

we take the time-derivative of the latter and identify $\nu^{-1} = \epsilon$, to get the second circuital equation

$$\epsilon\dot{\mathbf{E}} = \nabla \times \mathbf{H}.$$

Introducing these definitions into (7.3.31), and associating the permeability with the density, we get the equation of motion,

$$\mu\dot{\mathbf{H}} = -\frac{1}{\epsilon}\nabla \times \mathbf{E} + \lambda\nabla(\nabla \cdot p^{-1}\mathbf{H}), \tag{7.3.32}$$

where we also set the rotational constant equal to the inverse of the dielectric constant, and p^{-1} is Heaviside's notation for the inverse of the time-derivative.

In respect to the first equation in [EM], there is an additional term in (7.3.32) which normally should be zero because

$$\nabla \cdot \mathbf{H} = \frac{1}{r\sin\vartheta}\frac{\partial \mathbf{H}}{\partial\varphi} = 0, \tag{7.3.33}$$

since $\mathbf{H}$ consists of circles on a sphere of constant latitude and has nothing to do with φ which measures longitude. It is also required that $\mathbf{H}$ be divergentless. Then, taking the time-derivative of (7.3.32), we get

$$\epsilon\mu\ddot{H} = \frac{1}{r}\frac{\partial^2}{\partial r^2}rH + \frac{1}{r^2}\frac{\partial}{\partial\vartheta}\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta H - \frac{1}{r^2\sin^2\vartheta}\frac{\partial^2 H}{\partial\varphi^2}. \tag{7.3.34}$$

The two numbers in quantum mechanics that describe angular momentum are ℓ and m, the angular momentum and its projection on the z-axis, respectively. For photons as well as elementary particles it is more convenient to consider the ℓ spin, and m helicity. The photon is a spin $\ell = 1$ particle, and a spin-one particle has $2\ell + 1$ states with $m = -1, 0, 1$. But not for a photon since a massless particle cannot have helicity $m = 0$. This is guaranteed by (7.3.33). But, if (7.3.33) does not hold, and $\mathbf{H}$ is periodic in φ, i.e. $e^{im\varphi}$, then for $m = \pm 1$, the last term in (7.3.34) cancels the term in the second expression that prevents it from being the Laplacian. In that

event (7.3.34) becomes

$$\epsilon\mu\ddot{H} = \frac{1}{r}\frac{\partial^2}{\partial r^2}rH + \frac{1}{r^2\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial H}{\partial\vartheta}\right), \tag{7.3.35}$$

for the $m = 0$ longitudinal mode.

Now, the right-hand side is not the expression for the Laplacian in spherical coordinates, which for the $m = 0$ state would read

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right).$$

But, it is the free-particle spatial part of the Schrödinger equation, for the same $m = 0$ state, which uses the radial part of the Laplacian in cylindrical coordinates. This has been derived from the circuital equations [EM], and not from the operator $p_r = -\mathrm{i}\hbar\partial/\partial r$ for the radial momentum. Moreover, the $m = 0$ mode corresponds to the spherical harmonic

$$\ell(\ell+1) = -\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta\frac{\partial}{\partial\vartheta},$$

with eigenvalue $\ell = 1$, which is the value of its spin, while

$$\ell(\ell+1) = -\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta\frac{\partial}{\partial\vartheta} + \frac{1}{\sin^2\vartheta},$$

corresponds to the same eigenvalue, but with $m = \pm 1$. It is only the former which is compatible with a space varying index of refraction.

By shifting the quantum numbers ℓ and m from angular and azimuthal quantum numbers to spin and helicity, we have obtained the equations governing photons and the corresponding $m = 0$ longitudinal mode. Heaviside certainly could not have foreseen all this, but he should have noted that he did not come out with the correct spherical harmonic in terms of Legendre polynomials, but, rather, with their first derivatives. There is a paucity of equations in physics, owing to the frugality of nature that requires their reinterpretation under different physical circumstances.

Heaviside began his investigation on trying to obtain condensation waves from the rapid oscillations of plus and minus charges in a conductor. Obviously since plane waves are incapable of longitudinal vibrations, he was led to consider the next in the order of simplicity — spherical waves. If electricity can be likened to a fluid, and if it were compressible then

it would naturally give rise to a condensation wave. This would make it unnecessary to consider an electric current as the motion through a space of something since the vibrations of a lattice would do equally well. For a constant index of refraction, Heaviside did not find any condensation waves.

If (7.3.14) has anything to do with gravity, it will be the Helmholtz equation for the wave function that determines the gravitational field once the additional potential Ω and index of refraction are specified. This is in contrast to Poisson's equation where the gravitational potential is determined by the mass density.

7.4 The Models

Our three basic models are:

(i) *The Flat Model*, where

$$E = 1, \qquad G = r^2,$$

for which the wave equation is:

$$\left(\frac{d^2}{dr^2} + \omega^2\eta^2 - \frac{\ell^2}{r^2}\right) u = 0, \tag{7.4.1}$$

where, without loss of generality, we consider a reduced scalar wave equation. Equation (7.4.1) bears a remarkable resemblance to the normal form of Bessel's equation, where a periodic solution exists for $r > \ell/\eta\omega$, and an exponentially damped solution for the reverse of the inequality.

Even more can be said when we introduce another equivalence principle

$$\frac{\ell^2}{r^2} = \omega^2 r^2, \tag{7.4.2}$$

which takes us from constant angular momentum, implying equal areas in equal times, to one of constant angular frequency. This has the effect of converting Bessel's equation (7.4.1) into the differential

equation for Hermite polynomials

$$\left(\frac{d^2}{dr^2} + \eta^2 - \omega^2 r^2\right) u = 0. \tag{7.4.3}$$

A periodic solutions exists if r stays in the limits $\pm\eta/\omega$.

(ii) *The Beltrami, or Projective, Model*, where

$$E = \frac{1}{(1 - r^2/R^2)^2}, \quad G = \frac{r^2}{1 - r^2/R^2}, \tag{7.4.4}$$

with R the absolute constant, or radius of curvature. The wave equation is

$$\left\{\frac{d^2}{dr^2} + \eta^2 - \frac{\ell^2}{r^2}\left(1 - \frac{r^2}{R^2}\right)\right\} \mathrm{u} = 0. \tag{7.4.5}$$

If the radius of curvature is $R = 1/\sqrt{\rho}$ [i.e. $R = c/\sqrt{(G\rho)}$], and the total mass, M is constant, rather than the mass density, ρ, (7.4.5) becomes

$$\left(\frac{d^2}{dr^2} + \eta^2 - \frac{\ell^2}{r^2}\left(1 - \frac{2M}{r}\right)\right) u = 0. \tag{7.4.6}$$

For a constant index of refraction, (7.4.6) will give the deflection of light about a massive body, M, while in the case where the index of refraction is given by (7.3.2), it will describe the advance of the perihelion.

(iii) *The Stereographic Inner Product Model*, where

$$E = \frac{1}{(1 - r^2/R^2)^2}, \quad G = \frac{r^2}{(1 - r^2/R^2)^2},$$

for which the wave equation is

$$\left(\frac{d^2}{dr^2} + \eta^2 - \frac{\ell^2}{r^2}\left(1 - \frac{r^2}{R^2}\right)^2\right) u = 0. \tag{7.4.7}$$

However, since the Gaussian curvature is no longer constant, this will cause a modification of the conservation of the angular momentum from

its Euclidean expression (7.3.13). It will now be given by

$$\ell = \frac{\dot{\varphi} r^2}{1 - r^2/R^2} = \frac{\dot{\varphi} r^2}{1 - 2M/r}, \tag{7.4.8}$$

where we transferred from one of constant density, ρ, to one of constant mass, M, since the absolute constant,

$$R = \sqrt{(3/8\pi\rho)}. \tag{7.4.9}$$

The absolute constant (7.4.9) is proportional to the free fall time, $\rho^{-1/2}$.

We did this so that (7.4.8) would correspond to Møller's [52] expression for the angular momentum that he got in his treatment of the perihelion shift. His conclusion that the right-hand side of (7.4.8) "cannot in general be interpreted as angular momentum, since the notion of a 'radius vector' occurring in the definition of angular momentum has an unambiguous meaning only in a Euclidean space." This space should rather be a space of constant curvature. We will return to this discussion in Sec. 9.6.

Transferring our attention to the phase $S = -\mathrm{i} \ln u + \text{const.}$, we get

$$S' = \pm\sqrt{(\eta^2 - \Omega)}, \tag{7.4.10}$$

in the optico-geometric limit where $\nabla^2 S \ll 1$. Equation (7.4.10) can be considered as the generalization of the Poisson equation of the short-wavelength theory of gravitation. The phase S plays the role of an action, and is known as the eikonal in geometrical optics. It is completely determined by the gravitational potential, in the case that the index of refraction is varying, and by the generalized centrifugal potential Ω. Gravitational effects will be reflected in deviations from the Flat Model for S, which is given by ($\eta = 1$)

$$\begin{aligned} S_\pm(r,\varphi) &= \int \dot{r}\, dr = \pm \int \frac{\sqrt{(r^2 - \ell^2)}}{r} dr \\ &= \pm\left(\sqrt{\left(r^2 - \ell^2\right)} - \ell \cos^{-1}\frac{\ell}{r} + \ell\varphi\right) \\ &= \pm\ell \int \tan^2\varphi\, d\varphi = \pm\ell(\tan\varphi - \varphi). \end{aligned} \tag{7.4.11}$$

The second line of (7.4.11) describes wavefronts characterized by the condition that $S_\pm = \text{const.}$, and are involutes of the circle $r = \ell$. Now, a

Fig. 7.2. Rays tangent to a circular caustic of radius l.

caustic is an envelope of a family of rays. The wavefronts are normal to the rays PA and PB, and the caustic curve coincides with the envelope AB of this family of normals in Fig. 7.2. The wavefronts are the involute to the curve AB. The envelope of the normal to this curve is called the evolute. The rays corresponding to the eikonal S_- are half-lines tangent to the circle $r = \ell$. The first term in S_- represents the length $PA - \sqrt{(r^2 - l^2)}$, while the second term is the arc length of AC. The negative sign in the former means that the direction of the ray is from P to A. An analogous explanation holds for S_+.

$\ell/2$ times S_+ in the last line of (7.4.11) represents the difference in areas of the triangle $\triangle AOB$, which is $\frac{1}{2}\ell^2 \tan\varphi$, and the area of the sector COB, $\frac{1}{2}\ell^2\varphi$, shown in Fig. 7.3. Thus, $S_+ > 0$ on the strength of the trigonometric inequality $\tan\varphi - \varphi > 0$, and represents distance.

Rays do not penetrate into the shadow region which in the interior of the caustic, $r < l$. In this region, the eikonal, (7.4.11), becomes completely imaginary,

$$S_\pm^\dagger = \mathrm{i}\left\{\ell \cosh^{-1}\left(\frac{\ell}{r}\right) - \sqrt{\left(\ell^2 - r^2\right)}\right\}. \tag{7.4.12}$$

Since the 'shadow' intensities vanish exponentially, they are usually ignored. But, because the matching conditions between periodic and aperiodic zones furnish the quantum conditions in quantum mechanics, they

Fig. 7.3. Sector inscribed in a triangle.

must have some physical meaning. In fact, we will see that the shadow region lies in hyperbolic space.

In the shadow zone we are no longer restricted to the relativistic assumption that nothing travels faster than the speed of light. Thus it is entirely feasible to have angular velocity $r\dot{\varphi} > 1$. The phase and group velocities are also problematic in quantum mechanics. Since their product is 1, if the group velocity is less than 1, the phase velocity must be greater than 1. But, this could be rationalized only by excluding their use in signal transmission since no optical effect could propagate faster than the speed of light.

Boundary conditions in general relativity usually require space-time to be asymptotically flat. But, in rotating systems, we will learn in Chapter 9 that a cut-off must be introduced for, otherwise, distances $r > 1/\dot{\varphi}$ would make the time component of the metric tensor negative. Distances greater than $1/\dot{\varphi}$ bring us into the caustic region, and since the region is hyperbolic, it does not lead to the Landau and Lifshitz [75] conclusion that "such a system cannot be made up of real bodies."

The action (7.4.12) can also be derived from Fermat's principle using an indefinite metric. The principle now asserts that

$$I = \int \eta\sqrt{\left(r^2\dot{\varphi}^2 - \dot{r}^2\right)}\,dt = \int \eta\sqrt{\left(r^2\varphi'^2 - 1\right)}\,dr \tag{7.4.13}$$

be stationary. Following the same procedure as given above, we find the trajectory is now given by

$$\varphi - \varphi_0 = \cosh^{-1}\left(\frac{l}{\eta r}\right),$$

for a constant index of refraction. We can always arrange that the integration constant $\varphi_0 = 0$ by fixing the initial point of the measurement of arc length. The extremum of (7.4.13) is just the negative of the hyperbolic distance

$$I = -\sqrt{\left[\ell^2 - (\eta r)^2\right]} = -\ell \tanh \varphi. \tag{7.4.14}$$

The extremum of the length of the ray is given by nothing less than the corresponding segment of the Lobachevsky straight line!

Canonical parametrization, where we set the radius of the caustic circle equal to ℓ, and the arc length $s = \sinh \varphi$, enable the profile curve to be written as:

$$\begin{aligned}\beta(s) = \big(g(s), h(s)\big) &= \left(\sinh^{-1} s - \frac{s}{\sqrt{(1+s^2)}}, \frac{1}{\sqrt{(1+s^2)}}\right) \\ &= \big(\varphi - \tanh \varphi, \operatorname{sech} \varphi\big).\end{aligned}$$

The term $g(s)$ measures the distance along the axis of revolution, and $h(s)$ measures the distance from the axis of revolution.

The action (7.4.12) is merely the distance along the axis of revolution, $S^\dagger = g(s)$, which in terms of φ is

$$S^\dagger = \ell \int \tanh^2 \varphi \, d\varphi = \ell\,(\varphi - \tanh \varphi)\,. \tag{7.4.15}$$

Equation (7.4.15) is the parametric equation for a tractrix, whose surface of revolution resembles a bugle, having Gaussian, constant negative curvature $-1/\ell^2$. The tangent to the tractrix which intersects the x-axis has the constant value ℓ, as shown in Fig. 7.4. The distance from the origin to the point of tangency along the x-axis is $\ell\varphi$. The point on the tractrix which has as a tangent intercepting the x-axis is located at a distance $\ell(\varphi - \tanh \varphi)$ along the x-axis. This is precisely the action (7.4.15).

In contrast to the bright zone, where the action is the difference in areas between a triangle and the sector in which it inscribes, in the shadow zone, it is the difference between the distance from the origin to the point of

Fig. 7.4. Newton's tractrix again.

intersection of tangent of the tractrix and the x-axis and the distance from the origin to the point of intersection of normal of the intersection point of the tractrix and its tangent to the x-axis, as shown in Fig. 7.4. Newton defined the tractrix as the curve for which the length of its tangent from the point of contact to the x-axis is constant. Huygens pointed out that this curve could be interpreted as the path of a dog which is pulled by a leash of length ℓ. Its primary importance is the role that it plays in hyperbolic geometry where its surface of revolution is the pseudosphere, as we have seen in Fig. 2.19.

We recall that the pseudosphere is the negative curvature counterpart of a sphere. One may wonder whether there is a closed figure like a sphere which exhibits negative constant curvature. In was proved by Hilbert at the turn of the twentieth century that there is no smooth unbounded surface of constant negative curvature in ordinary space. Nevertheless, a plane of negative curvature can be obtained by introducing an indefinite metric.

7.5 General Relativity versus Non-Euclidean Metrics

...we have no proof of the need for a curved universe (space plus time) and the physical meaning of this theory is very confusing
[Brillouin 70]

We may generalize the foregoing analysis to non-Euclidean geometries by writing Fermat's principle using the first fundamental form,

$$I = \int \eta \sqrt{\left(E\,dr^2 + G\,d\varphi^2\right)} = \text{extremum}.$$

The fundamental form is a Clairut parametrization which is an orthogonal parametrization where E and G depend only on r. Then since φ is a

Obs. Fig. 7.4 → estudar e adaptar à minha realidade.

cyclic coordinate, we obtain the *pre-geodesics*, or a curve of zero geodesic curvature as

$$\frac{d\varphi}{dr} = \pm\frac{\ell\sqrt{E}}{\sqrt{G}\sqrt{(\eta^2 G - \ell^2)}}, \tag{7.5.1}$$

regardless of whether the index of refraction is a constant or not. As we have already said, the angular momentum ℓ gives the slant of the pre-geodesic curve.

We will determine E and G from the projective metric of a spherical distance on a sphere of radius R, and then let R become imaginary. This will give us a hyperbolic metric of constant curvature, which is obviously the Beltrami metric. Then, as a final step we will consider the mass as constant and not its density. This will have the effect of going to a metric of non-constant curvature [cf. (7.4.9)].

The line element on a sphere of radius R is

$$ds^2 = R^2\left(d\vartheta^2 + \sin^2\vartheta\, d\varphi^2\right). \tag{7.5.2}$$

As is shown in Fig. 7.5, the point P at (R, ϑ, φ), where the azimuthal, φ, is measured around the vertical axis, is projected stereographically onto the plane at point Q with coordinates (r, φ). Thus,

$$\vartheta = 2\tan^{-1}\frac{r}{2R},$$

whose differential is

$$d\vartheta = \frac{dr}{1 + r^2/4R^2}.$$

Fig. 7.5. The stereographic projection of a point on the sphere P onto the plane at point Q.

Introducing this into the expression for the line element (7.5.2) results in

$$ds^2 = \frac{dr^2}{(1 + r^2/4R^2)^2} + \frac{r^2\, d\varphi^2}{1 + r^2/4R^2}, \tag{7.5.3}$$

where we have used

$$\sin\vartheta = 2\sin\frac{1}{2}\vartheta\ \cos\frac{1}{2}\vartheta = \frac{r/R}{1 + r^2/4R^2}.$$

Expression (7.5.3) is the metric of the sphere as measured by the coordinates (r, φ) in the plane

$$\tan\frac{1}{2}\vartheta = \frac{r}{2R}.$$

Now, letting the radius become imaginary, $R \to \mathrm{i}R$, the metric for a sphere, (7.5.3), transforms into

$$ds^2 = \frac{dr^2}{(1 - r^2/4R^2)^2} + \frac{r^2\, d\varphi^2}{1 - r^2/4R^2}, \tag{7.5.4}$$

which identifies the coefficients E and G in the orthogonal, first fundamental form. This is none other than the Beltrami metric that we first met in Sec. 2.4.

So the metric for a sphere in elliptic space becomes the metric for a pseudosphere in hyperbolic space when $R \to \mathrm{i}R$.

Finally, as far as gravity is concerned, (7.5.4) sets the radius of curvature proportional to the density, (7.4.9). The Gaussian curvature, which has the dimension of inverse square length, is thus proportional to the density. But, (7.4.9) says more.

Of the three tests of general relativity, it is the gravitational redshift which is a consequence solely of the equivalence principle, and not of the gravitational field equations. It says that clocks will be slowed down in a gravitational field by an amount

$$t' = \surd\left(1 - u^2\right)t = \surd\left(1 - \omega^2 r^2\right)t = \surd\left(1 - \frac{2M}{r}\right)t,$$

where t' is the observer's proper time, and ω is the angular velocity of rotation. If the density, and not the mass is constant, the last inequality

states

$$\omega = \sqrt{\left(\frac{8\pi}{3}\rho\right)},$$

where $\rho^{-1/2}$ is proportional to the Newtonian free fall time. If the equivalence principle,

$$2M = \omega^2 r^3, \tag{7.5.5}$$

holds, all the results we get with $M = \text{const.}$, should follow with $\rho = \text{const.}$,

With the total mass $M = \text{const.}$, but not $\rho = \text{const.}$, (7.5.4) becomes

$$ds^2 = \frac{dr^2}{(1-2M/r)^2} + \frac{r^2\,d\varphi^2}{1-2M/r}, \tag{7.5.6}$$

where we used $M = 4\pi\rho r^3/3$. The Gaussian curvature of the surface,

$$K = -\frac{M}{r^3}\left(2 - 3\frac{M}{r}\right), \tag{7.5.7}$$

becomes constant, in the large r limit, when the density, ρ, does. Since $K = \kappa_1\kappa_2 = LN/EG$, where κ_1 and κ_2 are the principal curvatures, and L and N are the orthogonal coefficients of the second fundamental form,

$$L\,dr^2 + N\,d\varphi^2.$$

The mean curvature,

$$H = \frac{1}{2}(\kappa_1 + \kappa_2) = \frac{1}{2}\left(\frac{N}{G} + \frac{L}{E}\right) = -\frac{1}{r}\left(1 - \frac{2M}{r}\right), \tag{7.5.8}$$

for $L = -(2 - 3M/r)/r(1 - 2M/r)^2$ and $N = M/(1 - 2M/r)$. We now compare this with the Schwarzschild metric for the exterior and interior solutions.

The planar line elements for the Schwarzschild metric are

$$ds^2_{\text{ext}} = \frac{dr^2}{1-2M/r} + r^2\,d\varphi^2, \tag{7.5.9a}$$

$$ds^2_{\text{int}} = \frac{dr^2}{1-r^2/R^2} + r^2\,d\varphi^2, \tag{7.5.9b}$$

for the exterior and interior regions, respectively. It would appear that (7.5.9a) and (7.5.9b) are related by the equivalence relation (7.3.7). However, the exterior metric has Gaussian curvature $K_{\text{ext}} = -M/r^3$, while the interior metric has Gaussian curvature $K_{\text{int}} = 1/R^3$. Thus,

by going from the exterior to the interior metric what was a surface of negative, non-constant curvature has become one of positive, constant curvature! Now it is well-known that a simple coordinate transformation can eliminate the singularity, $r = 2M$ in (7.5.9a), and the solution can be continued all the way to $r = 0$. But, in no way would we expect that the curvature of the surface changes as we go from the exterior metric, (7.5.9a), to the interior metric, (7.5.9b). This does not happen in the Beltrami metric for when the principle of equivalence is applied, the curvature becomes $K = -1/R^2$.

The radial equation obtained from (7.5.1) for the Beltrami metric is

$$\dot{r} = \pm\frac{r^2}{\ell}\sqrt{\left[\eta^2 - \frac{\ell^2}{r^2}\left(1 - \frac{2M}{r}\right)\right]}, \tag{7.5.10}$$

and the angular momentum is conserved, $\ell = r^2\dot{\varphi}$. In the case of the deflection of light by a massive body $\eta = \text{const.}$, while in the advance of the perihelion, the refractive index is given by (7.6.1) where $W < 0$ would correspond to a complex index of refraction.

We can read off from (7.5.10) the potential,

$$2\Phi_S = -\frac{2M}{r} + \frac{\ell^2}{r^2}\left(1 - \frac{2M}{r}\right), \tag{7.5.11}$$

which we shall refer to as Schwarzschild's, and which is shown in Fig. 7.6 (b). The corresponding Newtonian potential, with $\ell = 0$, is shown in Fig. 7.6 (a). For $W < 0$, the Newtonian orbits are elliptic and the line $W = \Phi_N$ in Fig. 7.6 (a) gives the maximum and minimum distances of the particle from the central mass. By contrast, for sufficiently large values of the angular momentum, the Schwarzschild potential has a maximum positive value, as shown in Fig. 7.6 (b). Particles with energy less than this value will not reach the origin. The minimum of Φ_S corresponds to a circular orbit.

Fig. 7.6. Comparison of the Newtonian potential (a) with that of the Schwarzschild potential (b). The former is obtained from the latter by setting $\ell = 0$.

The radial equation of the Beltrami metric with non-constant curvature, i.e. constant mass, gives the coupling between rotational repulsion and gravitational attraction that allows the exact calculation of the perihelion shift.

General relativity gives the non-conserved angular momentum (7.4.8) and the equation for the radial coordinate as [Møller 52, p. 349]

$$\dot{r} = \pm\sqrt{\left(A + \frac{2M}{r} - r^2\dot{\varphi}^2\right)},$$

which upon inserting (7.4.8) becomes

$$\dot{r} = \pm\left[A + \frac{2M}{r} - \frac{\ell^2}{r^2}\left(1 - \frac{2M}{r}\right)^2\right]^{1/2}, \tag{7.5.12}$$

where A is a constant. By contrast, the Beltrami metric conserves the angular momentum, $\ell = r^2\dot{\varphi}$, and gives a radial equation,

$$\dot{r} = \pm\sqrt{\left[\eta^2 - \frac{\ell^2}{r^2}\left(1 - \frac{2M}{r}\right)\right]}, \tag{7.5.13}$$

which differs from (7.5.12) by the last term. But, since we are usually working at weak fields, we may take $(1-2M/r)^2 \approx 1-4M/r$, and in the same approximation neglect the second term in the denominator of (7.4.8). But, general relativity comes out with the equation of the trajectory as [Møller 52, Eqn. (28) p. 350]

$$\frac{1}{r^4}\left(\frac{dr}{d\varphi}\right)^2 = 2A + \frac{2M}{r} - \frac{\ell^2}{r^2} + \frac{2M\ell^2}{r^3} \tag{7.5.14}$$

which is what we would get from dividing (7.5.13) by $r^2\dot{\varphi}$, where the index of refraction $\eta = \surd(2A + 2M/r)$. Notwithstanding the final equation that general relativity uses, there should have been a discrepancy of a factor of 2 in the last term of (7.5.14).

So we may ask where do the general relativistic results come from? Consider a generalization of the inner product. It was Riemann's idea to generalize the ordinary dot product of two tangent vectors, $\mathbf{v}\cdot\mathbf{w}$ to the inner product,

$$\mathbf{v}\circ\mathbf{w} = \frac{\mathbf{v}\cdot\mathbf{w}}{g^2}.$$

In the xy-plane, the inner product is blown up by the factor

$$g = 1 - \frac{x^2+y^2}{R^2},$$

where R is the radius of the disc lying in the xy-plane. This geometric surface is the hyperbolic plane, and, necessarily, we must have $r = \surd(x^2+y^2) < R$. Transforming to polar coordinates, the line element is given by

$$ds^2 = \frac{dr^2 + r^2 d\varphi^2}{(1 - r^2/R^2)^2}, \tag{7.5.15}$$

which just misses being the stereographic projection given by the Beltrami metric (7.5.4) by being a factor of g too high in the denominator of the second term.

On the strength of the equivalence principle, (7.5.5), we can write (7.5.15) as

$$ds^2 = \frac{dr^2 + r^2 d\varphi^2}{(1 - 2M/r)^2}. \tag{7.5.16}$$

The equation for the pre-geodesic is

$$\frac{d\varphi}{dr} = \frac{\dot{\varphi}}{\dot{r}} = \pm\frac{\ell(1-2M/r)}{r^2\sqrt{\left[\eta^2 - \frac{\ell^2}{r^2}(1-2M/r)^2\right]}}. \tag{7.5.17}$$

Although this equation splits up into the general relativistic expression for the angular momentum, (7.4.8), and the radial equation, the latter will give twice the value for the rotational-gravitational coupling that (7.5.12) gives in the weak field approximation. This is on account of the fact that it is the same G coefficient in the fundamental form that appears in (7.4.8) and the radial equation.

The Schwarzschild exterior solution corresponds exactly to the stereographic metric, (7.5.15) under the transformation (7.5.5).

This is the reason for the inability to integrate their equation for the pre-geodesics. Remarkably, (7.5.17), under the equivalence principle, (7.5.5), is one of the few cases which can be integrated in closed form. For a constant index of refraction, and setting $R = 2$, it becomes

$$\frac{d\varphi}{dr} = \pm\frac{\ell(1-r^2/4)/r^2}{\sqrt{\left[1-\left(\ell(1-r^2/4)/r\right)^2\right]}}.$$

In order to perform the integration we set [O'Neill 66]

$$u = \frac{b}{r}\left(1+\frac{1}{4}r^2\right), \quad \text{where } b = \frac{\ell}{\sqrt{(1+\ell^2)}}.$$

This reduces the pre-geodesic to

$$d\varphi = \pm\frac{du}{\sqrt{(1-u^2)}},$$

so that the solution is

$$r^2 + r_0^2 - 2r_0 r\cos(\varphi - \varphi_0) = r_1^2,$$

where φ_0 is a constant of integration, and $r_0^2 = r_1^2 + 4$ is a Euclidean circle. The center of the circle, O, having coordinates (r_0, φ_0) lies outside the disc since $r_0 > 2$. The center O of this circle has an arc that cuts the rim orthogonally as shown in Fig. 7.7. All geodesics of the hyperbolic plane are either

Fig. 7.7. Geodesic curves that cut the rim of the hyperbolic plane orthogonally are arcs of a circle whose center O lies outside the disc.

curved arcs that cut the disc orthogonally or straight lines through the center. If we reinstate the constants, the condition that ℓ be real is $\omega r_0 > c$, and such a condition violates the limiting value of the speed of light. The fact that the curved geodesics are fixed by coordinates outside of the hyperbolic plane appears to resemble Mach's principle whereby rotation should be reckoned by the distribution of all the masses that make up the universe.

7.6 The Mechanics of Diffraction

Still considering a flat metric where coefficients of the first fundamental form are $E = 1$ and $G = r^2$, the simplest generalization is to consider a varying index of refraction,

$$\eta = \sqrt{\left(2W + \frac{2M}{r}\right)}, \tag{7.6.1}$$

for a closed orbit having negative total energy, $W < 0$. In the short-wavelength limit, the gravitational potential in (7.6.1) will have the effect of converting the phase of the Bessel function into a Laguerre function. The equation for the pre-geodesic is

$$\frac{d\varphi}{dr} = \pm\frac{\ell}{r^2\sqrt{\left(-2|W| + 2M/r - \ell^2/r^2\right)}}. \tag{7.6.2}$$

With the conservation of the angular momentum, the equation for the radial coordinate is

$$\frac{dS}{dr} = \dot{r} = \pm\sqrt{\left(-2|W| + \frac{2M}{r} - \frac{\ell^2}{r^2}\right)},$$

by definition of the eikonal, S. Now, introduce the change of variable, $x = 2r\sqrt{|W|}$ to obtain

$$\frac{dS}{dx} = \pm\sqrt{\left(-\frac{1}{4} + \frac{\lambda}{x} - \frac{\ell^2}{x^2}\right)},$$

where $\lambda = M/\sqrt{|W|}$. Its square can be approximated as

$$\left(\frac{dS}{dx}\right)^2 = \frac{\lambda}{x(1+\ell^2/\lambda x)} - \frac{1}{4} = \frac{\lambda}{x}\left(1 - \frac{\ell^2}{\lambda x}\right) - \frac{1}{4}.$$

With another change of variable, $x = 4\lambda\cos^2\vartheta - \ell^2/\lambda$, we get

$$\frac{dS}{dx} = \pm\frac{1}{2}\tan\vartheta. \tag{7.6.3}$$

Noting that $dx = -8\lambda\cos\vartheta\sin\vartheta\, d\vartheta$, we integrate to obtain

$$S = \pm\lambda(2\vartheta - \sin 2\vartheta). \tag{7.6.4}$$

With $\lambda^{\frac{1}{3}}$ as the absolute constant, π times (7.6.4) is precisely the volume of a sphere of radius $\rho = \lambda^{1/3}\vartheta$ in elliptic geometry. The surface distance is proportional to the angle ϑ subtended at the center so that ϑ can be used as a measure of surface distance. As ϑ increases the object you are viewing decreases in apparent size until it arrives at the equator, $\vartheta = \pi/2$. This is the maximum distance in elliptic geometry but not in spherical geometry. Increasing ϑ still further, the object now seems to be approaching and growing in size until it reaches $\vartheta = \pi$. On completion of the round trip, you return to the north pole but with your head facing in the opposite direction. The elliptic plane is thus said to have only one side at [Thurston 97]!

The finiteness of lines is the most novel feature of spherical geometry, and no line can be longer than π. Felix Klein suggested not to consider the whole sphere, but only half of it. This suggestion was made in order to eliminate the one, trivial, blemish of spherical geometry: any two great circles on a sphere meet not just in one point, but two diametrically opposite points, the so-called antipodes. By restricting the distance to $\pi/2$ the halves

of great circles meet only once. Consider two identical twins placed at antipodal points on each of the hemispheres. The twins regard themselves as a single entity and are not aware of the split. When any one of the twins moves, the other will also move to keep them diametrically separated. Each twin necessarily regards a pair of antipodal points on the sphere as a single location so that to him every pair of two great circles intersects at a single point, while to us it looks like two different points. When one twin traces out a triangle we see two antipodal triangles being traced out. To us Euclideans everything seems to double! This spherical flatland is called elliptic space, and so is superior to spherical geometry.

Quite remarkably and unexpectedly, by quantizing,

$$\lambda = n\hbar,$$

we come out with the energy levels of the hydrogen atom,

$$W = -\left(\frac{M}{n\hbar}\right)^2,$$

albeit mass replacing charge. Moreover, the Clairaut equation (7.6.2) is easily integrated to give

$$r = \frac{\ell^2/M}{1-(\Delta/M)\sin\vartheta}, \tag{7.6.5}$$

where $\Delta = \sqrt{(M^2 - 2|W|\ell^2)}$. This is the equation for an ellipse since the eccentricity,

$$\epsilon = \left(1 - \frac{2|W|\ell^2}{M^2}\right)^{1/2} = \left[1 - 2\left(\frac{\ell}{n\hbar}\right)^2\right]^{1/2} < 1. \tag{7.6.6}$$

The lengths of the major and minor axes, M and $\sqrt{(2|W|)}\ell$, clearly show the competing forces of gravitational attraction and centrifugal repulsion.

The transition point occurs where $S'(x_0) = 0$, which is

$$x_0 = \frac{(2n\hbar)^2 - \ell^2}{n\hbar}.$$

For $x > x_0$, or equivalently,

$$r > \frac{(2n\hbar)^2 - \ell^2}{2M}, \tag{7.6.7}$$

there is a transition to the exponential region, where (7.6.4) transforms into

$$S_{\pm}^{\dagger} = \pm\lambda(\sinh 2\vartheta - 2\vartheta). \tag{7.6.8}$$

With the same absolute constant $\lambda^{\frac{1}{3}}$, π times (7.6.8) is volume of a sphere with hyperbolic radius $\lambda^{1/3}\vartheta$. But, this is exactly what we should have expected since the transformation from spherical to hyperbolic geometry is achieved by letting the radius become imaginary, $\vartheta \to \mathrm{i}\vartheta$.

It is intriguing to know how the hydrogen atom would behave in a hyperbolic plane. Rearranging inequality (7.6.7) we get

$$\frac{2M}{r} + \frac{\ell^2}{r^2} > \left(\frac{2n\hbar}{r}\right)^2,$$

showing that gravitation and centrifugal forces no longer oppose one another. The gravitational potential would become repulsive, and for the hydrogen atom it would mean a repulsive Coulomb potential; the atom would fly apart.

All effects that we have so far discussed are nonrelativistic because c has not made its appearance. Their small corrections to celestial mechanics is fully accounted for by the Beltrami metric of hyperbolic geometry, as we shall now go on to show.

7.6.1 *Gravitational shift of spectral lines*

In Sec. 3.8.2.3 we saw how Einstein replaced the Doppler expression by a new one which predicted the effect that gravity would have upon spectral lines. That is, he replaced the nonrelativistic expression for the Doppler shift,

$$\frac{\nu - \nu_0}{\nu_0} = -u/c, \tag{7.6.9}$$

by

$$\frac{\nu - \nu_0}{\nu_0} = -\alpha/2r. \tag{7.6.10}$$

The confirmation of (7.6.10) is indeed miraculous, given its derivation. We know that motion causes a shift in the frequency, so the right-hand side should be u/c, the relativity velocity. But, if light from an unaccelerated frame is emitted, it will arrive at the accelerated frame in time h/c,

whose acceleration is being caused by gravity. So we want to replace u/c by gh/c^2, where g is the uniform acceleration on the Earth's surface. Finally, we want to replace this scenario with one by a (Newtonian) gravitational potential which depends on the mass and has an inverse dependency on distance. The factor of one-half in (7.6.10) is meant to show that we are in the non-relativistic region. So, we have gone from the Doppler effect which depends only on the speed to one in which mass and distance have entered. The Doppler shift, (7.6.9) can also lead to a blueshift if the object is approaching. The gravitational shift cannot occur for what was attraction would now become repulsion.

7.6.2 *The deflection of light*

Gravity makes the medium optically denser in the vicinity of a large mass, like the Sun, than it would be in its absence. As a result, light rays will be bent toward the Sun rather than being straight lines. As we know from Sec. 3.8.2 this effect was originally predicted by Söldner as far back as 1801; it was rediscovered by Einstein [52] in 1911 by *redefining* the Doppler effect.

The remarkable thing is that the equation for the trajectory of a light ray in a gravitational field can be derived directly from the Beltrami metric once we transform from a constant free-fall time, or frequency, to one of constant mass. This is not to be taken as a physical equivalence, but, rather, a mathematical one. However, the transformed metric of non-constant curvature is as 'physical' as the original Beltrami metric of constant curvature.

> The Beltrami metric at constant curvature describes a uniformly rotating disc, while the same metric at non-constant curvature describes the deflection of light in a gravitational field. The two are related by the mathematical statement of the equivalence principle.

Nothing could be so simple nor so beautiful. The rest of the analysis is standard; but, for completeness sake we reproduce it here.

We first introduce the change of variable, $r = \rho^{-1}$, in the pre-geodesic for the Beltrami metric, (7.5.10), to obtain

$$\frac{d\rho}{d\varphi} = \pm\sqrt{\left(\ell^{-2} - \rho^2 + 2M\rho^3\right)}. \tag{7.6.11}$$

Obs.: The Deflection of Light → interessante !!! Veja Beltrami metric at constant curvature.

This identical to the general relativistic equation for the trajectory (7.5.14) with $A = 0$. Second, we introduce another new variable, $\sigma = \rho\ell\sqrt{(1-2M\rho)}$, and neglecting the small term, $2M\rho^3$ we get

$$\varphi = \int_0^\rho \frac{\ell\, d\rho}{\sqrt{(1-\ell^2\rho^2)}} = \sin^{-1}\ell\rho.$$

The geodesic $r = \ell/\sin\varphi$, obtained by setting the constant of integration, $\varphi_0 = \pi/2$, is a straight line which passes through the origin at a distance ℓ when $\varphi = \pi/2$, and goes to infinity for $\varphi \to 0, \pi$.

The exact equation (7.6.11) may be cast in the form,

$$\frac{d\rho}{d\varphi} = \frac{\sqrt{(1-\sigma^2)}}{\ell}, \tag{7.6.12}$$

where $\sigma = \ell\rho\sqrt{(1-2M\rho)}$. Since $2M\rho$ is a small quantity, we can use the approximations:

$$\sigma = \ell\rho\,(1-M\rho)\,, \quad \ell\rho = \sigma\,(1+M\rho) = \sigma\,(1+M\sigma/\ell)\,,$$

which are valid to first-order. Differentiating we find $\ell\, d\rho = (1+2M\sigma/\ell)d\sigma$. Introducing these approximations into (7.6.12), and integrating we get

$$\begin{aligned}\varphi &= \int_0^\rho \frac{\ell\, d\rho}{\sqrt{(1-\sigma^2)}} = \int_0^\sigma \frac{(1+2M\sigma/\ell)d\sigma}{\sqrt{(1-\sigma^2)}} \\ &= \arcsin\sigma - \frac{2M}{\ell}\sqrt{(1-\sigma^2)} + \frac{2M}{\ell}.\end{aligned}$$

It is apparent from (7.6.12) that φ will have an extremum when $\sigma = 1$. This value corresponds to the closest approach of the ray to the Sun. At this distance the angle φ will be $\varphi_m = \pi/2 + 2M/\ell$. Reinstating all constants we find the total deflection to be

$$2\varphi_m - \pi = \frac{4GM}{\ell c}, \tag{7.6.13}$$

which is twice that obtained by treating the interaction through a Newtonian potential, as in Fig. 7.6 (a). The ratio of angular momentum to the speed of light, ℓ/c, plays the role of a collision parameter, or the closest distance approach. As expected, (7.6.13) is the ratio of the Schwarzschild radius to a characteristic length, here the collision parameter.

We can now show that the time of propagation along a ray will be lengthened in the presence of a massive body. Since the angular momentum has its Euclidean value, $\ell = \dot{\varphi} r^2$, in the Beltrami model, the action can be read off from (7.5.13) as

$$S_{\pm} = \pm \int \frac{\sqrt{[r^2 - \ell^2(1 - 2M/r)]}}{r} dr,$$

for $\eta = 1$. Treating the last term in the numerator as a small quantity we have

$$\begin{aligned} S_{\pm} &\approx \pm \int \frac{\sqrt{(r^2 - \ell^2)}}{r} \left[1 + \frac{M\ell^2}{r(r^2 - \ell^2)} \right] dr \\ &= \pm \left\{ \sqrt{(r^2 - \ell^2)} \left(1 + \frac{M}{r} \right) - \ell \cos^{-1} \frac{\ell}{r} \right\}. \end{aligned}$$

The length and the time it takes to propagate along a ray will be lengthened by the amount M/r, for small values of the gravitational potential. The deflection of light attests to this lengthening by *curving* the ray.

7.6.3 *Advance of the perihelion*

We treated the advance of the perihelion in Sec. 3.8.2 by the elegant method devised by Ritz. The only blemish is that the arbitrary parameter appearing in his force law had to be chosen to give the observational result. In this section we determine the advance by our optico-gravitational approach. By doing so we go against the adage of Boltzmann who said that elegance should be left to tailors and cobblers.

Taking into account both the gravitational potential and the quadrupole interaction, the index of refraction can be written as

$$\eta = \left[-2W + \frac{2M}{r} \left(1 + \frac{\ell^2}{r^2} \right) \right]^{1/2}.$$

In the unperturbed state, where the quadrupole interaction is absent, the gravitational potential must be large enough to produce a real eccentricity,

(7.6.6). The corresponding action over a period of the motion,

$$S(r,l) = \oint \frac{\sqrt{(\eta^2 r^2 - \ell^2)}}{r} dr$$
$$= \oint \left[-2W + \frac{2M}{r} - \frac{l^2}{r^2} + \frac{2M\ell^2}{r^3} \right]^{1/2} dr, \qquad (7.6.14)$$

shows that a closed trajectory will result from a dynamic balance between gravitational and centrifugal forces.

The quadrupole interaction requires $r > 3M$ in order that the angular momentum be real at the extremum of the potential $d\Phi_S/dr = 0$,

$$\ell^2 = \frac{Mr^2}{r - 3M},$$

as seen in Fig. 7.6(b). Introducing this fact into (7.6.14) by writing $r' = r+3M$, and retaining only those terms that are at most quadratic in M, give

$$S(r,\ell) = \oint \left[-2W + \frac{2M}{r}\left(1 - \frac{3M}{r}\right) - \frac{\ell^2}{r^2}\left(1 - \frac{6M}{r}\right) - \frac{2M\ell^2}{r^3} + \cdots \right]^{1/2} dr,$$

where for brevity we have dropped the prime on r. Expanding the integrand in powers of the small correction terms results in

$$S = S^{(0)} - 3M^2 S^{(1)}, \qquad (7.6.15)$$

where the unperturbed action is

$$S^{(0)} = \oint \sqrt{\left(-2W + \frac{2M}{r} - \frac{\ell^2}{r^2}\right)} dr = 2\pi \left(\frac{M}{\sqrt{(2W)}} - \ell \right)$$

and first-order correction is

$$S^{(1)} = \oint \frac{dr}{r\sqrt{(-2Wr^2 + 2Mr - \ell^2)}} = -\frac{2\pi}{\ell}.$$

Since the trajectory is defined by the equation,

$$\varphi + \frac{\partial S}{\partial \ell} = \text{const.},$$

the change in the angle φ over one revolution is

$$\Delta\varphi = -\frac{\partial \Delta S}{\partial \ell}$$

$$= 2\pi + 3M^2 \frac{\partial S^{(1)}}{\partial \ell}$$

$$= 2\pi \left(1 + \frac{3M^2}{\ell^2}\right). \tag{7.6.16}$$

General relativity gives the shift as $6\pi M/l$, where l is the semi-latus rectum. From the equation of the ellipse, we find $l = \ell^2/M$ so that (7.6.16) is the exact same expression found in general relativity. This is also comparable to Ritz's result (3.8.22), which we will do in a moment.

The rotation of the perihelion of Mercury per revolution amounts to 0.104″. The dimensionless total energy constant $W = 2.59 \times 10^{-8}$, and the mean motion $\omega = \ell/ab = (2W)^{3/2}/M = 8.34 \times 10^{-7}\ \mathrm{s}^{-1}$, where $a = M/2W$ and $b = \ell/\sqrt{(2W)}$ are the semi-major the semi-minor axes. The calculated period of Mercury is $\tau = 2\pi/\omega = 87.25$ days, which is close to the actual value of $\tau = 88$ days. The frequency of rotation of the perihelion is $\Delta\omega = \omega\Delta\varphi_1 = 4.25 \times 10^{-13}\ \mathrm{s}^{-1}$.

This approach can be compared to Ritz's calculation of the advance of the perihelion in Sec. 3.8.2. Ritz begins with his law of force, and finds it necessary to consider that angular momentum is not conserved. This he shares with general relativity. Rather, the Beltrami metric does not lead to any violation of the conservation of angular momentum. The transform from a metric of negative constant curvature to non-constant curvature uses (7.5.5). General relativity would use half that because the metric they use is the stereographic metric, (7.5.15). The factor of 2 enters in when the quadratic term is approximated by a linear one.

It is not the numerical factors which make or break a theory. In non-Euclidean geometries the unit of measurement is left at discretion. This allays any suspicion that new metrics must be invented to account for the optico-gravitational phenomena.

Chapter 8

Relativity of Hyperbolic Space

Of course, since Einstein, we do not use hyperbolic geometry to model the geometry of the universe.
[Greenberg 93]

8.1 Hyperbolic Geometry and the Birth of Relativity

Almost immediately after the birth of special relativity, Sommerfeld [09] made the interesting observation that the relativistic composition laws of velocities are "no longer the formulas of the plane but those of spherical trigonometry (with imaginary sides)" — trigonometrical formulas obtained by replacing the real argument by an imaginary one. Spheres of imaginary radius had been known for a long time, as this identity was pointed out by Lobaschevsky [98] himself. The first explicit connection of Lobaschevsky geometry to relativity was made by Varićak [10]. The hyperbolic geometry of relativity represents the velocity addition law as a triangle on the surface of a pseudosphere — a surface of revolution looking like a bugle [cf. Fig. 2.19] — and the angle of parallelism [cf. Fig. 2.12], which measures the deviation from Euclidean space. As the relative velocity approaches unity, the angle of parallelism approaches zero. The fact that the angle of parallelism provides a unique relation between circular and hyperbolic functions can be found in the early textbook on relativity by Silberstein [14] written in 1914. These developments did not have a follow up, and no place for hyperbolic geometry could be found in the relativity textbooks that followed. Undoubtedly, this was due to the influence of Einstein's general relativity which is based upon Riemann geometry, where matter and geometry are woven together.

Yet, even more astonishing is that Poincaré missed all of this! Over fifty years after the discovery of the hyperbolic geometry, Poincaré developed

two models of hyperbolic geometry: The upper half-plane and disc models that we discussed in Sec. 2.4. The inhabitants of hyperbolic plane, Poincarites, consider geodesics as straight lines while to us Euclideans they would appear as circular arcs meeting the boundary orthogonally in the disc model, and see Poincarites shrink as they approach the real axis from the upper half-plane. Poincarites would not be able to measure their shrinkage because the rulers they use shrink along with them.

These distortions are created by motion, and Poincaré was well aware of the contraction that bodies undergo in the direction of the Earth's motion, of an amount proportional to the square of the aberration. This is the famous FitzGerald–Lorentz contraction that was first postulated independently by FitzGerald and Lorentz, as an explanation of the Michelson–Morley null result, which we discussed in Sec. 3.2. Poincaré [05] was also aware of the relativistic velocity composition law, since it was he who discovered it. Yet, he did not recognize that the longitudinal Doppler law *is* the invariant cross-ratio if the velocity in that law is that resulting from the relativistic *subtraction* law.

Measurements in relativity consist in sending and receiving light signals. Distances are measured in terms of time differences. At each step, the time it takes to receive a signal sent out at a previous time is itself times a factor which turns out to be the longitudinal Doppler shift [Whitrow 33]. The space-time transformations from one inertial frame to another, involving Doppler shifts, combine to give the Lorentz transformation [Milne 48]. Had Poincaré realized that his definition of hyperbolic distance in terms of the logarithm of the cross-ratio, which for the distance between any two velocity points on a vertical half-line with an endpoint at infinity, is proportional to the logarithm of the longitudinal Doppler shift, he could have carried over the battery of concepts and tools he developed some twenty years before relativity — without distinguishing between the 'special' and 'general' theories of Einstein. This we plan to do in this chapter.

The chapter is organized as follows. We discuss in Sec. 8.2 the connection between geometrical rigid motions and their relations to particular inertial frames of reference. Compounding Doppler shifts at different velocities yields the Poincaré composition law, which, in terms of homogeneous coordinates shows that the Lorentz transform is a unique Möbius

automorphism that exchanges an inertial frame of equal and opposite velocities with the state at rest. We will also appreciate it as the isomorphism that converts the Poincaré model to the Klein, or projective, model of the hyperbolic plane, as well as establishing the limit for hyperbolic rotations in terms of the angle of parallelism.

We then discuss in Sec. 8.3 the relativistic phenomenon of aberration and show that it conforms to the hyperbolic law of sines. In terms of a right triangle inscribed in a unit disc, angular deformations of the non-central angle and contractions of the side of the triangle perpendicular to the motion will respectively be related to the facts that the sum of the angles of a hyperbolic triangle is less than π, and that a FitzGerald–Lorentz contraction in the direction normal to the motion making it look like more of a rotation than a contraction.

The hyperbolic contraction is in the direction *normal* to the motion, and *not* in the direction of the motion. It is exactly the same second-order Doppler effect that Ives and Stilwell measured back in 1938, as we have described in Sec. 3.4. Ives considered it as a demonstration that clocks in motion run slower, and has nothing to do with a relativistic time dilatation.

The radar method of sending and receiving light signals to measure elapses in time and distance will then be used in Sec. 8.4 to contrast states of uniform motion and uniform acceleration. We confirm Whitrow's [80] conclusion that acceleration does, indeed, affect the rate of a clock, and convert his inequality for time dilatation into an equality for systems in uniform acceleration. The characteristic means that we find for times of reflection for systems in uniform motion and uniform acceleration imply different temporal scales.

Applications to general relativity and cosmology follow. Beltrami coordinates and logarithmic time are used to derive a metric first investigated by Friedmann which corresponds to 'dust-like' matter at zero pressure in terms of Einstein's energy–momentum tensor. A comparison with the 'general' relativity then follows in Sec. 8.5. In Sec. 8.6 we unveil the hyperbolic geometry of relativity, and generalize it to multidimensional velocity space in Sec. 8.7. The Friedmann–Lobaschevsky space finds confirmation in Hubble's discovery of the redshift in the spectra of galaxies: The greater the shift the more distant the galaxy. This we show in Sec. 8.9 is a consequence of the hyperbolic measure of the

velocity, and its relation to the logarithmic scale of time through Hubble's law.

8.2 Doppler Generation of Möbius Transformations

It has long been known [Silberstein 14] that the relativistic composition of velocities obeys hyperbolic geometry. Robb [11] proposed to call the Euclidean measure of the velocity,

$$u = \tanh \bar{u}, \tag{8.2.1}$$

the 'rapidity,' where u is the relative velocity, having set the absolute constant $c = 1$. We can invert (8.2.1) to find the expression

$$\bar{u} = \frac{1}{2} \ln \left(\frac{1+u}{1-u} \right) = \frac{1}{2} \ln \{u, 0 | -1, 1\}, \tag{8.2.2}$$

for the hyperbolic measure of the relative velocity $\bar{u}$, which unlike its Euclidean counterpart is not confined to the closed interval $[-1, 1]$.

Recall from Sec. 2.2.4 that the curly brackets represent the cross-ratio of the distance between x and y in the closed interval $[a, b]$,

$$\{a, b | x, y\} = \frac{(a-x)(b-y)}{(a-y)(b-x)}. \tag{8.2.3}$$

Exponentiating both sides of (8.2.2) shows that the exponential of the hyperbolic length is given by the longitudinal Doppler shift,

$$e^{\bar{u}} = \left(\frac{1+u}{1-u} \right)^{1/2} =: K. \tag{8.2.4}$$

We will now show that compounding Doppler shifts generates Möbius transforms thereby relating geometric rigid motions with specific inertial frames.

And just as Poincaré found, these linear fractional functions can be used to *define* the concept of length under which the polygons of the respective tessellation are of equal size.

Veja: 8.2.4 → analisar K.
Interessante!!!!

Preliminarily, compounding the Doppler shift at velocity u with itself gives

$$\left(\frac{1+u}{1-u}\right) = \left(\frac{1+\lambda}{1-\lambda}\right)^{1/2},$$

where λ is the relative velocity in an inertial frame comprised of equal and opposite velocities

$$\lambda = \frac{2u}{1+u^2} = \tanh(2\bar{u}). \tag{8.2.5}$$

Next, consider the cross-ratio,

$$\{v, \lambda | -1, 1\} = \frac{1+v}{1-v} \cdot \frac{1-\lambda}{1+\lambda} = \frac{1+v'}{1-v'}.$$

The 'new' relative velocity v' is given in terms of the 'old' one by

$$v' = \frac{v-\lambda}{1-\lambda v}, \tag{8.2.6}$$

which will be easily recognized as the relativistic *subtraction* law of the velocities.

Introducing the second equality in (8.2.5) to (8.2.6) gives the familiar Lorentz 'rotation,'

$$v = \frac{v' \cosh(2\bar{u}) + \sinh(2\bar{u})}{v' \sinh(2\bar{u}) + \cosh(2\bar{u})},$$

in terms of the homogeneous coordinates v and v'.

Multiplying (8.2.6) out gives

$$v'v + \lambda^{-1}(v - v') - 1 = 0. \tag{8.2.7}$$

Two cases are of interest: If the relative velocities are equal, $v = v'$, (8.2.7) becomes the simplest hyperbolic involution with conjugate points at ± 1 [cf. Sec. 2.2.5.2]. This is not of physical interest; rather, what is of physical interest is when the velocities are equal and opposite, $v = -v'$. For then (8.2.7) reduces to the quadratic form,

$$v^2 - 2\lambda^{-1}v + 1 = 0,$$

which has two real roots

$$v_{\pm} = \frac{1 \pm \sqrt{(1-\lambda^2)}}{\lambda}.$$

Since the relative velocity λ is given by (8.2.5), the two roots are $v_+ = 1/u$ and $v_- = u$.

The negative of (8.2.6),

$$\mathcal{M}_\lambda(v) = \frac{v-\lambda}{\lambda v - 1}, \tag{8.2.8}$$

is the unique Möbius automorphism which exchanges λ and 0, viz. $\mathcal{M}_\lambda(\lambda) = 0$ and $\mathcal{M}_\lambda(0) = \lambda$. This can be recognized as a special case of the property that $\mathcal{M}_\lambda$ is involutory: $\mathcal{M}_\lambda \circ \mathcal{M}_\lambda = \mathcal{I}$, the identity.

A Möbius transform takes any triplet (v_1, v_2, v_3) into any other triplet. The demonstration of the existence of such a transform rests on showing that there is a Möbius transform for which $\mathcal{M}(v_1) = 0$, $\mathcal{M}(v_2) = 1$ and $\mathcal{M}(v_3) = \infty$. The values are not only the range of the conjugate points, u and $1/u$, but, moreover, allow the Möbius transform to be written as the invariant cross-ratio

$$\mathcal{M}(v) = \{v, v_2 | v_1, v_3\} = \frac{(v-v_1)}{(v-v_3)} \cdot \frac{(v_2-v_3)}{(v_2-v_1)}.$$

Thus, by the construction of the cross-ratio, we have $\mathcal{M}(v_1) = 0$, $\mathcal{M}(v_2) = 1$, and $\mathcal{M}(v_3) = \infty$.

If we identify $\mathcal{M}$ with (8.2.8) then the triplet $(0, 1, \infty)$ occurs when $v_1 = \lambda$, $v_2 = 1$, and $v_3 = 1/\lambda$. The latter would imply that v is unbounded which contradicts special relativity. It is the symmetry of the hyperbolic involution which implies that if u is a solution, then so is $1/u$. We must therefore show that the conjugate point v_+ is a repulsive fixed point, implying that repeated mappings of $\mathcal{M}_\lambda$ repel it away from v_+.

The Möbius transform F conjugating the normalized $\mathcal{M}_\lambda$ to its standard form sends v_+ to zero and v_- to infinity,

$$F(v) = \frac{v - v_+}{v - v_-},$$

with

$$F^{-1}(v) = \frac{-v_- + v_+}{-v+1}.$$

Rather than calculate the composition $F \circ \mathcal{M}_\lambda \circ F^{-1}(z)$ to find the standard form of $\mathcal{M}_\lambda$, it suffices to calculate it at a point $F^{-1}(1) = \infty$ so that $\mathcal{M}_\lambda(\infty) = 1/\lambda$, and $F(1/\lambda) = -1$. Thus,

$$F \circ \mathcal{M}_\lambda \circ F^{-1}(v) = e^{i\pi} v, \tag{8.2.9}$$

is the standard form of $\mathcal{M}_\lambda$, and represents a rotation about the fixed point v_- which interchanges λ with O.

The Möbius transformation (8.2.8) is therefore elliptic. Several properties are immediate: v_+ is the inverse of v_- with respect to the circle of inversion C_1 in Fig. 8.1. The fixed point v_- lies inside the unit disc and the other fixed point v_+ lies outside except when $v_- = v_+$, and then they both lie on the circle of inversion. Fixed points closer and closer to the center send their conjugates points further and further away. Inversion takes circles orthogonal to the original one into themselves. Two such orthogonal circles, C_1 and C_2, are shown in Fig. 8.1. The line ℓ joining their centers has the fixed points diametrically opposite lying on the circumference of the circle C_2 whose center is $O_2 = \lambda^{-1}$. The arcs of C_2 lying in C_1, and orthogonal to it at the points of contact correspond to geodesics in the Poincaré model.

Fig. 8.1. Circles of inversion. The circle C_1 cuts the circle of inversion C_2 at right angles at P and Q. A line from the origin of C_1 intersects C_2 at two points: v_- and its inverse v_+, which are fixed points of the Lorentz transform. The relative velocity λ lies at an equal hyperbolic distance from v_+ that v_- lies from the origin. A hyperbolic rotation of π occurs about v_- which exchanges the state of uniform velocity λ and the state of rest at O_1.

Fig. 8.2. A more detailed description of the circle containing the fixed points v_1 and λ which are uniform states of motion at relative velocities u and $2u/(1+u^2)$. The Möbius automorphism of the disc may be considered as a composition of two hyperbolic rotations: A rotation of π about the hyperbolic midpoint between the origin and λ, and a rotation about the origin. The maximum angle ϕ is determined by the angle of parallelism, Π, beyond which no motion can occur.

The intersection of the arc PQ with the line ℓ, shown in Fig. 8.2, occurs at the hyperbolic midpoint, $\bar{v}_- = u$, between 0 and λ. This is a direct consequence of the definition of hyperbolic distances: Whereas the hyperbolic distance from 0 to λ is

$$h(0,\lambda) := \{-1,1|\lambda,0\} = \ln\left(\frac{1+\lambda}{1-\lambda}\right) = 2\ln\left(\frac{1+u}{1-u}\right),$$

the distance from 0 to $\bar{v}_-$ is half as great

$$h(0,\bar{u}) = \{-1,1|u,0\} = \ln\left(\frac{1+u}{1-u}\right).$$

The arc PQ is itself the perpendicular bisector of $O\lambda$. The Möbius transformation (8.2.8) is the composition of two hyperbolic reflections in perpendicular lines through v_-. Moreover, it is the unique Möbius automorphism that exchanges O and λ by a rotation through π about the hyperbolic midpoint v_- of the hyperbolic line segment.

Expression (8.2.5) is the isomorphism that takes the Poincaré model to the Klein model. Both are hyperbolic models of the unit disc, but whereas the Poincaré model is conformal the Klein model is not. The price to be

paid is that geodesics in the Poincaré model are arcs of circles that cut the unit disc orthogonally, while the geodesics in the Klein model are straight lines. The isomorphism λ maps the arc with ends P and Q onto the open chord with the same endpoints. Since v_- is the point where line ℓ cuts the circumference of the orthogonal circle C_2, $\lambda(v_2) = \lambda(\bar{u})$ is the point at which the line ℓ intersects the chord PQ. But this is precisely the definition (8.2.5) of λ.

When the orthogonal arcs intersect, there occurs a hyperbolic rotation. At the limit when they are asymptotic, there is a limit rotation while when they become ultraparallel there is a hyperbolic translation. However, hyperbolic translations in hyperbolic velocity space would contradict the fact that the limiting velocity is that of light. Consider the right triangle $O\lambda Q$ formed by the intersection of lines ℓ and ℓ_c in Fig. 8.2. The angle at the origin Π is the limiting angle, or the angle of parallelism that we introduced in Sec. 2.5. For angles less than φ, the angle of parallelism will not be reached. Consequently, ℓ_c is the limiting line for hyperbolic rotations. According to the right triangle, $\cos \Pi = \bar{\lambda}$, while according to the Bolyai–Lobaschevsky formula for the radian measure of the angle of parallelism,

$$\Pi(\bar{\lambda}) = 2 \tan^{-1} \, \mathrm{e}^{-\bar{\lambda}}. \tag{8.2.10}$$

The angle $\Pi(\bar{\lambda})$ is a sole function of the *hyperbolic* distance $\bar{\lambda}$. The closer it is to $\pi/2$, the less pronounced the hyperbolic distortions become. Thus,

$$\cos \Pi(\bar{\lambda}) = \tanh \bar{\lambda} = \frac{2v_-}{1 + v_-^2}$$

is just the isomorphism of the Poincaré model onto the Klein model. Since Π must necessarily be acute, hyperbolic translations are ruled out, and the limiting rotation occurs for asymptotes.

8.3 Geometry of Doppler and Aberration Phenomena

Consider the triangle in Fig. 8.3 with sides $\bar{\alpha}$ and $\bar{\delta}$, and base $\bar{u}$. The altitude $\bar{h}$ cuts the base into two parts $\bar{\varepsilon}$ and $\bar{u} - \bar{\varepsilon}$. The angles formed from the sides and the base are $\bar{\vartheta}$ and $\bar{\varphi}$. The sines of these angles are

$$\sin \bar{\vartheta} = h/\alpha = \frac{\tanh \bar{h} \operatorname{sech} \bar{\varepsilon}}{\tanh \bar{\alpha}} = \frac{\sinh \bar{h}}{\sinh \bar{\alpha}},$$

Poincaré model are arcs...

Fig. 8.3. Extension of hyperbolic trigonometry to general triangles.

and

$$\sin\bar{\varphi} = h/\delta = \frac{\tanh\bar{h}\,\mathrm{sech}(\bar{u}-\bar{\varepsilon})}{\tanh\bar{\delta}} = \frac{\sinh\bar{h}}{\sinh\bar{\delta}},$$

since deformation only occurs normal to the direction of motion, i.e. $\bar{u}$.

Introducing the hyperbolic Pythagorean theorem of the first triangle,

$$\cosh\bar{\alpha} = \cosh\bar{\varepsilon}\,\cosh\bar{h},$$

into the hyperbolic Pythagorean theorem for the second triangle,

$$\cosh\bar{\delta} = \cosh\bar{h}\cosh(\bar{u}-\bar{\varepsilon}) = \cosh\bar{h}(\cosh\bar{u}\cosh\bar{\varepsilon} - \sinh\bar{\varepsilon}\sinh\bar{u}), \tag{8.3.1}$$

results in

$$\cosh\bar{\delta} = \cosh\bar{\alpha}\cosh\bar{u} - \tanh\bar{\varepsilon}\sinh\bar{u}\cosh\bar{\alpha}. \tag{8.3.2}$$

Finally, introducing $\cos\bar{\vartheta} = \tanh\bar{\varepsilon}/\tanh\bar{\alpha}$ gives the hyperbolic law of cosines

$$\cosh\bar{\delta} = \cosh\bar{u}\cosh\bar{\alpha} - \sinh\bar{\alpha}\sinh\bar{u}\cos\bar{\vartheta}. \tag{8.3.3}$$

In an exactly analogous way we find

$$\cosh\bar{\alpha} = \cosh\bar{\delta}\cosh\bar{u} - \sinh\bar{\delta}\sinh\bar{u}\cos\bar{\varphi}. \tag{8.3.4}$$

Now, introducing $\cos\bar{\vartheta} = \tanh\bar{\varepsilon}/\tanh\bar{\alpha}$ into $\cos\bar{\varphi} = \tanh(\bar{u}-\bar{\varepsilon})/\tanh\bar{\delta}$ results in

$$\tanh\bar{\delta}\cos\bar{\varphi} = \frac{\tanh\bar{u} - \tanh\bar{\alpha}\cos\bar{\vartheta}}{1 - \tanh\bar{u}\tanh\bar{\alpha}\cos\bar{\vartheta}}. \tag{8.3.5}$$

But, this should be a velocity composition law [cf. Fig. 8.4 where the triangle has to be fitted on a surface of a pseudosphere rather than the flat Euclidean

Fig. 8.4. Hyperbolic velocity triangle.

plane], and it will become one when we introduce the velocity components $u_1 = \alpha = \tanh \bar{\alpha}$, and $u_2 = \delta = \tanh \bar{\delta}$.

Inserting these definitions into (8.3.5) gives

$$u_2 \cos \bar{\varphi} = \frac{u - u_1 \cos \bar{\vartheta}}{1 - u u_1 \cos \bar{\vartheta}}. \tag{8.3.6}$$

Equation (8.3.6) is the equation of aberration in the direction of the motion. In the limit as $\bar{\alpha}, \bar{\gamma} \to \infty$, $u_1, u_2 \to 1$, and they become light signals.

The hyperbolic cosine law, (8.3.3), can be written as

$$\frac{\sinh \bar{\delta}}{\sinh \bar{\alpha}} = \frac{\tanh \bar{\delta}}{\tanh \bar{\alpha}} \cosh \bar{u} \left(1 - \tanh \bar{\alpha} \tanh \bar{u} \cos \bar{\vartheta}\right) = \frac{\sin \bar{\vartheta}}{\sin \bar{\varphi}}, \tag{8.3.7}$$

which is the hyperbolic law of sines,

$$\frac{\sin \bar{\vartheta}}{\sinh \bar{\delta}} = \frac{\sin \bar{\varphi}}{\sinh \bar{\alpha}}, \tag{8.3.8}$$

showing that sides can be expressed in terms of angles in hyperbolic geometry [Buseman & Kelly 53]. The hyperbolic law of sines, (8.3.8), happens also to be the equation of aberration normal to the motion,

$$u_2 \sin \bar{\varphi} = \frac{u_1 \sin \bar{\vartheta} \sqrt{(1 - u^2)}}{1 - u u_1 \cos \bar{\vartheta}}. \tag{8.3.9}$$

Taking the differential of (8.3.6),

$$-\sin \bar{\varphi}\, d\bar{\varphi} = \frac{u_1}{u_2} \frac{\gamma^{-2} \sin \bar{\vartheta}}{(1 - u u_1 \cos \bar{\vartheta})^2}\, d\bar{\vartheta}, \tag{8.3.10}$$

and introducing (8.3.9) result in

$$d\bar{\varphi} = -\frac{\sqrt{(1-u^2)}}{1-u\tanh\bar{\varepsilon}}d\bar{\vartheta}, \tag{8.3.11}$$

where we used $\tanh\bar{\alpha}\cdot\cos\bar{\vartheta} = \tanh\bar{\varepsilon}$. Dividing both sides by the time increment gives the Doppler shift as

$$\nu = K\nu_0, \tag{8.3.12}$$

where

$$K = \frac{\sqrt{(1-u^2)}}{1-uu_1\cos\bar{\vartheta}} \tag{8.3.13}$$

is the Doppler factor. A moving object emits a signal at frequency $\nu_0 = d\bar{\vartheta}/dt$ with velocity u_1, and $\nu = -d\bar{\varphi}/dt$ is the frequency that the observer at rest registers.

If the signal is emitted at the velocity of light, $u_1 = 1$, implying that $\bar{\alpha} \to \infty$, and $\bar{\vartheta} \to \pi/2$, or equivalently $\bar{\varepsilon} \to 0$, it follows from (8.3.3) that $\bar{\delta} \to \infty$ such that the difference $\bar{\delta} - \bar{\alpha}$ remains finite

$$\mathrm{e}^{(\bar{\delta}-\bar{\alpha})} = \cosh\bar{u} = \frac{1}{\sqrt{(1-u^2)}}. \tag{8.3.14}$$

The Doppler shift (8.3.12) then becomes the *exponential* Doppler shift,

$$\nu = \mathrm{e}^{-(\bar{\delta}-\bar{\alpha})}\nu_0. \tag{8.3.15}$$

An exponential law for the longitudinal Doppler shift is known [Prohovnik 67], but not for the transverse redshift. The exponential law would imply that the frequency and energy of light received from receding galaxies depend on an exponential factor which would decrease the luminosity and explain things like Olber's paradox, where the decrease in the intensity of the source (inverse square of the distance) is exactly balanced by the increase in the number of sources (square of the distance).

The linear approximation,

$$\frac{\Delta\nu}{\nu_0} = -(\bar{\delta}-\bar{\alpha}) = -\frac{1}{2}u^2, \tag{8.3.16}$$

equates the redshift with the distance, $\bar{\delta} - \bar{\alpha}$, and with the second-order relative velocity, obtained by expanding (8.3.14) to first-order. If u is the

Earth's orbital velocity (3×10^4 m/sec), (8.3.16) would predict a frequency shift of $(\bar{\delta} - \bar{\alpha}) = 5 \times 10^{-9}$.

Ordinarily, one writes the Doppler factor (8.3.13) with $u_1 = 1$ without realizing that it requires the limit $\bar{\alpha} \to \infty$, which, in turn, requires that it be normal to the motion. That is, the Doppler shift (8.3.13) is

$$K = (\cosh \bar{u} - \sinh \bar{u} \ \cos \bar{\vartheta})^{-1}.$$

In the line of sight, we get the longitudinal shift $K = e^{\bar{u}}$, while normal to our sight it becomes (8.3.15). Thus, there is a shift even in the normal direction. However, for $\bar{\vartheta} \neq 0$, the shift will not be exponential, and consequently the 'distance' will not be given by the Lobaschevsky straight line. In this sense, the Lobaschevsky straight line is the 'shortest distance.'

Aberration equations (8.3.6) and (8.3.9) can be combined in the half-angle formula, $\tan \bar{\varphi}/2 = \sin \bar{\varphi}/(1 + \cos \bar{\varphi})$ to read

$$\tan \bar{\varphi}/2 = \left(\frac{1-u}{1+u}\right)^{1/2} \cot \bar{\vartheta}/2 = e^{-\bar{u}} \cot \bar{\vartheta}/2. \tag{8.3.17}$$

Equation (8.3.17) will give the well-known expression for angle of parallelism: The ratio of concentric limiting arcs between two radii is the exponential distance between the arcs divided by the radius of curvature. Something very strange occurs at $\bar{\varphi} = \pi/2$. For we then obtain from (8.3.17),

$$\tan \bar{\vartheta}/2 = e^{-\bar{u}}, \tag{8.3.18}$$

showing that $\bar{\vartheta}$ is the angle of parallelism. The angle becomes a sole function of the hyperbolic distance, $\bar{u}$. An observer in the frame in which the object is at rest will see it rotated by an amount $\sin \bar{\vartheta} = \sqrt{(1 - u^2)}$, exactly equal to the FitzGerald–Lorentz contraction, as we will see in Sec. 10.5. Since the angle of parallelism provides a unique link between circular and hyperbolic functions, a rotation and contraction can only be related at the angle of parallelism, if the geometry is indeed hyperbolic. The equivalence of rotations and contractions was first discussed by Terrell [59], but his analysis cannot be extended to the situation where the angle is not acute; the angle of parallelism must always be acute, tending to a right angle only in the limit of Euclidean geometry, as the velocity of light, $c \to \infty$.

8.4 Kinematics: The Radar Method of Signaling

With the realization that there is no such thing as a rigid body in relativity, Whitrow [33] went on to develop a radar method, or what he called a 'signal-function method,' where light signals are transmitted between different inertial frames and non-inertial ones. It was afterward referred to as the 'K-calculus technique' by Bondi [60] without a hint of where the original idea came from, and Milne [48] used it extensively in his research prior to him. In fact, the original idea and the definition of rapidity can be traced all the way back to Robb [11] in 1911.

8.4.1 *Constant relative velocity: Geometric-arithmetic mean inequality*

As in kinematic relativity [Milne 48], time measurements are much more fundamental than distance measurements, and the latter are deducible from the former. In other words, distances are measured by the lapse of time. This has been criticized by Born [43] as being impractical since no one has ever received light signals from nebulae beyond the horizon. However, it is far superior to the usual method in general relativity that uses a metric, or rigid ruler, to measure distance. So what was discarded in special relativity made its come back in general relativity.

The most ideal situation would be to introduce into the fabric of the theory distances measured in brightness, or the difference between apparent and absolute brightness. However, no one has ever succeeded in doing so and we will base all distance measurements on the so-called radar method, where a light signal is sent out and reflected at a later time. All that is needed is that at each reflection a certain retardation factor, K, comes in, determined by the clock in the frame that is sending out the light pulse.

Consider two observers, A and B, where observer A sends out a light signal in his time t_1^A which is received by observer B in his time t_2^B. In terms of A's time, B will receive it in time Kt_1^A, where K is some constant factor that is a function only of the relative velocity of the two inertial frames. The signal that arrives at B in time t_2^B will be reflected at some later time. The reflected signal leaves B in time t_3^B which arrives at observer A in time t_4^A, where $t_4^A = Kt_3^B$. From this it is apparent that both observers will call the

reflection time,

$$t^r = \sqrt{(t_1^A t_4^A)} = \sqrt{(t_2^B t_3^B)}, \tag{8.4.1}$$

the geometric mean of the time intervals, and it is an invariant independent of the frame. The appearance of the geometric mean, as opposed to the arithmetic mean, implies implicitly the existence of another time scale, namely, a logarithmic one [cf. Eq. (8.4.30) below]. So the 'signal-function method' of Whitrow singles out the geometric mean as the time of reflection.

The reading shown by a synchronous (stationary) clock at the event should be midway between the observer's time, t_1^A, of sending out the signal, and the time he receives its reflection, t_4^A,

$$t = \frac{1}{2}(t_1^A + t_4^A). \tag{8.4.2}$$

This was Einstein's choice, but it is by no means the only choice. The measure of the space interval is the difference between the 'average' for the light-signaling process, (8.4.2), and the time the signal was sent out,

$$r = t - t_1^A = \frac{1}{2}(t_4^A - t_1^A). \tag{8.4.3}$$

In terms of B's coordinates, he will measure a time interval

$$t' = \frac{1}{2}(t_2^B + t_3^B), \tag{8.4.4}$$

and a space interval

$$r' = \frac{1}{2}(t_3^B - t_2^B), \tag{8.4.5}$$

separating the event from where he is located. The two systems of inertial coordinates (t, r) and (t', r') are related by

$$t_2^B = t' - r' = K(t - r) = Kt_1^A, \tag{8.4.6a}$$

$$t_3^B = t' + r' = K^{-1}(t + r) = K^{-1}t_4^A. \tag{8.4.6b}$$

The time t_2^B is the time on B's clock when the signal is received, and t_3^B is the moment on B's clock when it is sent back.

If B reflects the signal instantaneously so that $t_2^B = t_3^B$ then from the second equalities in (8.4.6a) and (8.4.6b) it follows that

$$K = \left(\frac{1 + r/t}{1 - r/t}\right)^{1/2} = \left(\frac{1 + u}{1 - u}\right)^{1/2}, \tag{8.4.7}$$

upon taking the positive square root, and setting $r/t = u$.

Now suppose we place ourselves at the origin of B's frame, $r' = 0$. Then summing (8.4.6a) and (8.4.6b) gives

$$t = \frac{1}{2}(t_1^A + t_4^A) = \frac{1}{2}(K + K^{-1})t' = \frac{t'}{\sqrt{(1 - u^2)}}, \tag{8.4.8}$$

showing that a clock traveling at a uniform velocity goes slower than one at rest. This expression for time dilatation only holds for frames moving at a constant velocity u [cf. Eq. (8.4.27) below].

In terms of the longitudinal Doppler shift, (8.2.4), the two systems of coordinates are related by

$$\begin{aligned} t &= \frac{1}{2}(t_1^A + t_4^A) = \frac{1}{2}(Kt_3^B + K^{-1}t_2^B) \\ &= \frac{1}{2}[(K + K^{-1})t' + (K - K^{-1})r'] \\ &= t' \cosh \bar{u} + r' \sinh \bar{u}, \end{aligned} \tag{8.4.9}$$

and

$$\begin{aligned} r &= \frac{1}{2}(t_4^A - t_1^A) = \frac{1}{2}(Kt_3^B - K^{-1}t_2^B) \\ &= \frac{1}{2}[(K - K^{-1})t' + (K + K^{-1})r'] \\ &= t' \sinh \bar{u} + r' \cosh \bar{u}. \end{aligned} \tag{8.4.10}$$

These are none other than the well-known Lorentz transformations. Taking their differentials and forming the difference of their squares show that the hyperbolic distance,

$$dt^2 - dr^2 = dt'^2 - dr'^2, \tag{8.4.11}$$

is invariant.

Now, we ask what happens when the light signal is reflected when it arrives at B. In this case, $t_2^B = t_3^B \equiv t^r$ is the time of reflection, and it occurs

at the same point in space for B so that $r' = 0$. The Lorentz transformations, (8.4.9) and (8.4.10), reduce to

$$t = t^r \cosh \bar{u}, \tag{8.4.12a}$$

$$r = t^r \sinh \bar{u}. \tag{8.4.12b}$$

Equation (8.4.12a) is a statement of the arithmetic-geometric mean inequality: The arithmetic mean t can never be inferior to the geometric mean t^r since $\cosh \bar{u} \geq 1$. Adding and subtracting (8.4.12a) and (8.4.12b) give

$$t + r = Kt^r, \tag{8.4.13a}$$

$$t - r = K^{-1}t^r. \tag{8.4.13b}$$

Taking the differentials of (8.4.13a) and (8.4.13b), and then the product of the two, without requiring that K be constant, result in

$$dt^2 - dr^2 = dt^{r\,2} - t^{r\,2}du^2. \tag{8.4.14}$$

A space-time interval has been transformed into a velocity space-time interval.

8.4.2 *Constant relative acceleration*

There is general consensus [Møller 52] that acceleration has no effect on the rate of a clock, and that the expression for time dilatation (8.4.8) can be used in its infinitesimal form whether or not u is constant. However, according to Einstein's equivalence principle uniform acceleration is equivalent to, or indistinguishable from, a uniform gravitational field. It has been shown from the gravitational redshift that the latter, indeed, has an effect on the rate of a clock. This contradiction has been clearly pointed out by Whitrow [80], who shows that the time dilatation is greater when the velocity is varying with time than when it is constant. We convert his inequality into an equality.

Consider two observers receding from one another with an average velocity r/t. Their identical clocks were synchronized at $t^A = t^B = 0$ when they were at the same point. At time t_1^A, A emits a signal which is picked up and immediately reflected by B at time $t^{B\,r}$, and then received back at A

at time t_3^A. The space interval is

$$t - t_1^A = t_3^A - t = \frac{1}{2}(t_3^A - t_1^A) = r.$$

From this it follows that

$$t_1^A = t - r, \tag{8.4.15a}$$

$$t_3^A = t + r, \tag{8.4.15b}$$

and consequently,

$$t^{Ar} = \sqrt{(1 - (r/t)^2)}\, t. \tag{8.4.15c}$$

Since the Doppler shift is now given by

$$K = \left(\frac{1+u}{1-u}\right)^{1/2} = \left(\frac{1+r/t}{1-r/t}\right) \tag{8.4.16}$$

and not by (8.4.7), we can express (8.4.15a) and (8.4.15b) as $t_3^A = Kt_1^A$, or

$$t^{Br} = K^{1/2} t_1^A, \tag{8.4.17a}$$

$$t_3^A = K^{1/2} t^{Br}. \tag{8.4.17b}$$

But, from (8.4.15c) it is apparent that $t^{Br} = t^{Ar}$ so that the clocks remain synchronized, and we can drop the superscripts on the time.

Expressing r and t in terms of t_1 and t_3 we find [Page 36]

$$g = 2\frac{r}{t^{r\,2}} = \frac{1}{t_1} - \frac{1}{t_3}, \tag{8.4.18}$$

where g is the uniform acceleration due to gravity. Employing (8.4.17a) and (8.4.17b) we write (8.4.18) as

$$g = \frac{K^{1/2} - K^{-1/2}}{t^r}. \tag{8.4.19}$$

Equation (8.4.18) enables us to express the Doppler shift, K, in terms of the ratio of the time the signal was received back to that when it was sent out

$$t_3/t_1 = K. \tag{8.4.20}$$

Taking the logarithms of both sides of (8.4.20), and then differentiating with respect to t, give

$$\frac{d\ln t_3}{dt} - \frac{d\ln t_1}{dt} = \frac{1+u}{t_3} - \frac{1-u}{t_1} = \frac{1}{1-u^2}\frac{du}{dt},$$

where we have used the differentials of (8.4.15a) and (8.4.15b). Dividing both sides by $\sqrt{(1-u^2)}$ results in

$$\frac{K}{t_3} - \frac{K^{-1}}{t_1} = \frac{1}{(1-u^2)^{3/2}}\frac{du}{dt} = g, \tag{8.4.21}$$

which is identical to (8.4.18). If the ratio (8.4.20) had been proportional to the square of the Doppler shift, we would have found that (8.4.21) vanishes.

If we consider t' to be the time of reflection on B's clock, we can write (8.4.18) as

$$\frac{1}{t_1} = \frac{1}{t'} + g/2, \tag{8.4.22a}$$

$$\frac{1}{t_3} = \frac{1}{t'} - g/2, \tag{8.4.22b}$$

which can easily be seen by subtraction. Rather, adding (8.4.22a) and (8.4.22b) gives

$$\frac{1}{t'} = \frac{1}{2}\left(\frac{1}{t_1} + \frac{1}{t_3}\right). \tag{8.4.23}$$

The time of reflection on B's clock is the *harmonic* mean for uniform acceleration, in contrast with the *geometric* mean as the time of reflection for uniform motion.

Writing $t_1 = t - r$ and $t_3 = t + r$ in (8.4.23) clearly shows that the space-time interval is not invariant

$$t^2 - r^2 = t't = t'^2,$$

unless we require the reflection times to be the same, meaning that clocks A and B are synchronous [Prohovnik 67].

Multiplying the left- and right-hand sides of (8.4.22a) and (8.4.22b), rearranging, taking the square roots, and using $gt = \sinh \bar{u}$, give

$$t' = \operatorname{sech}(\bar{u}/2)t' = \operatorname{sech}^2(\bar{u}/2)t, \tag{8.4.24}$$

where the second equality follows from (8.4.15c). The equalities in (8.4.24) express quantitatively that the harmonic mean is always smaller than the geometric mean which is smaller than the arithmetic mean, because the equality of times can never apply. The first equality in Eq. (8.4.24) states physically that the time of reflection on B's clock is always less than on A's clock.

Taking the ratio of (8.4.22a) and (8.4.22b) we get

$$K = \frac{t_3}{t_1} = \frac{1 + gt'/2}{1 - gt'/2}. \tag{8.4.25}$$

Instead of (8.4.7), we now have

$$\frac{1}{2}gt' = r/t = \tanh \bar{u}/2. \tag{8.4.26}$$

Differentiating with respect to the arithmetic time average gives

$$\begin{aligned} g\,dt' &= \operatorname{sech}^2 \bar{u}/2 \,\frac{d\bar{u}}{dt}dt \\ &= \frac{\operatorname{sech}^2 \bar{u}/2}{1 - u^2}\frac{du}{dt}dt \end{aligned}$$

and now using (8.4.21), gives

$$dt = \cosh^2(\bar{u}/2)\frac{dt'}{\sqrt{(1 - u^2)}}. \tag{8.4.27}$$

Comparing (8.4.27) with the expression for time dilatation for uniform motion, (8.4.8), leads to the inescapable conclusion that

> clocks will run even slower in a uniformly accelerating frame than in an inertial frame when viewed from a stationary frame. The consensus of opinion that acceleration will have no effect upon the apparent rate of clocks is inaccurate.

The transformation laws (8.4.17a) and (8.4.17b) can be expressed as

$$t + r = K^{1/2} t^r, \tag{8.4.28a}$$

$$t - r = K^{-1/2} t^r. \tag{8.4.28b}$$

Taking the differentials of (8.4.28a) and (8.4.28b), and then their product, result in

$$\begin{aligned} ds^2 := dt^2 - dr^2 &= dt^{r\,2} - \frac{1}{4} t^{r\,2} (d \ln K)^2 \\ &= dt^{r\,2} - \frac{1}{4} t^{r\,2} d\bar{u}^2. \end{aligned} \tag{8.4.29}$$

The appearance of $t^{r\,2}$ in the velocity space component of the metric (8.4.29) implies uniform expansion, and solicits the introduction of logarithmic time,

$$\tau = 2\tau_0 \ln (t^r / \tau_0), \tag{8.4.30}$$

where τ_0 is an absolute constant, into (8.4.29) so that

$$ds^2 = dt^2 - dr^2 = \frac{e^{\tau/\tau_0}}{4} \{d\tau^2 - \tau_0^2 \, d\bar{u}^2\}. \tag{8.4.31}$$

Thus, the formulas of the transformation of coordinates (8.4.28a) and (8.4.28b) can be written as

$$t + r = \tau_0 e^{\tau/\tau_0 + \bar{u}/2}, \tag{8.4.32a}$$

$$t - r = \tau_0 e^{\tau/\tau_0 - \bar{u}/2}. \tag{8.4.32b}$$

These equations clearly show that logarithmic time, (8.4.30), is *hyperbolic* time. At constant t^r, a surface of revolution is obtained by rotating the hyperbola $t^2 - r^2 = t^{r\,2}$ around the t axis to give a bowl-shaped form. As it should, the relative velocity, $\bar{u}$, vanishes in the metric.

The equivalence relations (8.4.32a) and (8.4.32b) can be combined to read

$$t + r = K(t - r), \tag{8.4.33}$$

which is the *square* of (8.4.7) for uniform motion. In fact, at constant velocity,

$$t + r = K(t' - r'), \tag{8.4.34a}$$

$$t - r = K^{-1}\left(t' + r'\right), \tag{8.4.34b}$$

we conclude that whereas (8.4.32a) and (8.4.32b) do not retain its invariant hyperbolic form the latter does

$$t^2 - r^2 = t'^2 - r'^2. \tag{8.4.35}$$

Adding and subtracting the equations yield the well-known Lorentz transformations (8.4.9) and (8.4.10), and from which it can be concluded that the Lorentz transformations leave invariant the hyperbolic 'distance' (8.4.35).

In terms of radar signaling, (8.4.33) consists in a single observer: A light pulse is emitted in time t_1, and observed by him at a later time $t_2 = Kt_1$. Alternatively, in the case of constant velocity, (8.4.34a) says a light signal is emitted at time t'_1, in the prime inertial frame, and observed in the unprimed frame at a later time $t_2 = Kt'_1$. Whereas, (8.4.34b) says that if a signal is emitted at time t_1, it will be observed at time t'_2 in the primed inertial frame.

For uniform motion the geometric mean time remains invariant,

$$\sqrt{(t_1 t_2)} = \sqrt{(t'_1 t'_2)}.$$

This is the same as requiring the hyperbolic line element (8.4.35) to be invariant. While, for uniform acceleration, the time of reflection in the B frame is the harmonic mean of the A frame. In his analysis of uniform acceleration, Page [36] attempted to show that the space-time interval between neighboring points is not constant. His analysis replaces (8.4.22b) by

$$\frac{1}{t_3} = \frac{1}{t''} - g/2. \tag{8.4.36}$$

This condition would necessarily imply that the harmonic means in the two frames are equal. Solving (8.4.22a) and (8.4.36) for the times t' and t'', with $t'' > t'$ we get

$$\tilde{t} := \frac{1}{2}(t' + t'') = t\,\mathrm{sech}^2(\bar{u}/2), \tag{8.4.37a}$$

$$\tilde{r} := \frac{1}{2}(t'' - t') = [r - t\tanh(\bar{u}/2)]\mathrm{sech}^2(\bar{u}/2). \tag{8.4.37b}$$

However, (8.4.37b) vanishes by the definition of the Lobaschevsky line segment [cf. (8.4.26)], and hence $\bar{r} = 0$. The time of reflection is given by the harmonic mean (8.4.23). Therefore, for uniformly accelerating systems the point of reflection must occur at the origin of B's frame, whose time is given by the harmonic mean of A's clock.

8.5 Comparison with General Relativity

We are convinced that purely mathematical reasoning can never yield physical results, that if anything comes out of mathematics it must have been put in in another form. Our problem is to find out where the physics got into the general theory.
Bridgman

Einstein's theory of relativity essentially consists of two principles [Fock 69, p. 233]: The unification of space and time into a four-dimensional space with an indefinite metric, and the relation of the curvature of the space to the presence of matter. Einstein also proposed an 'equivalence' principle between inertia and gravitational mass, or between acceleration and gravitation. The latter has been criticized by Fock [69, pp. 232, 233]. With a constant index of refraction, gravitational considerations appear only in the specification of the absolute constant, which is related to the constant, negative curvature of the hyperbolic space.

A centrifugal potential appears explicitly in the flat metric whereas the gravitational potential does not.

In the general case of non-uniform motion the relevant space is the Lobaschevsky–Friedmann velocity space [Fock 69, Sec. 94], which can, and will in Sec. 8.6, be derived without any appeal to Einstein's equations, and the unphysical assumption that matter must be 'dust-like' at zero pressure. Even dust exerts pressure! We will see in Sec. 8.7 velocity components are related to the sides of a Lambert quadrilateral whose Weierstrass coordinates of the point of the acute angle show that the geometric mean time enters as a magnification of these coordinates, and not as a separate entity. Most importantly, by avoiding the 'rigid scaffolding' employed by Einstein, which is applicable to inertial frames of reference only [Fock 69], acceleration has been accounted for as changes in velocity space, where the independence of the 'coordinates' and time has disappeared. But before

embarking on our journey into hyperbolic space let us pause to see how general relativity accounts for a state of constant acceleration.

The general theory is based on the significance of an indefinite metric tensor, which sets gravity propagating at the speed of light or beyond [cf. below]. Space-time is labeled by a four-dimensional set of coordinates x^i for which three of the coordinates label the position of the event in space, while the fourth one fixes the time coordinate. In general relativity these labels have no physical significance. The proper distances are fixed by the metric tensor,

$$ds^2 = g_{ij}\, dx^i\, dx^j, \tag{8.5.1}$$

where the Einstein convention of summing over repeated indices has been used. The metric tensor, (8.5.1), says that if x^i and $x^i + dx^i$ are labels for two events in space-time then ds will be their proper distance between the two events. If it turns out that $ds^2 > 0$, then the two labels are separated by a time-like interval whereas if $ds^2 < 0$, the labels are separated by a space-like interval.

The metric tensor determines the geodesics of a freely moving particle. They can be derived from Fermat's principle of least time. If we consider the proper time interval $[\tau_1, \tau_2]$, then the variational principle states

$$\delta \int_{\tau_1}^{\tau_2} ds = \delta \int_{\tau_1}^{\tau_2} \sqrt{\left(g_{ij} \frac{dx^i}{d\tau} \frac{dx^j}{d\tau} \right)}\, d\tau,$$

or equivalently,

$$\int_{\tau_1}^{\tau_2} \left[\frac{d}{d\tau} \left(g_{ik} \frac{dx^k}{d\tau} \right) - \frac{1}{2} \frac{\partial g_{kl}}{\partial x^i} \frac{dx^k}{d\tau} \frac{dx^l}{d\tau} \right] \delta x^i\, d\tau = 0.$$

This must be zero for all virtual variations δx_i which vanish at the endpoints. That means that the Euler–Lagrange equations,

$$\frac{d}{d\tau} \left(g_{ij} \frac{dx^j}{d\tau} \right) - \frac{1}{2} \frac{\partial g_{kl}}{\partial x^i} \frac{dx^k}{d\tau} \frac{dx^l}{d\tau} = 0, \tag{8.5.2}$$

must be satisfied at each instant of proper time. In the case of constant gravitational acceleration along the x-axis, the coefficients of the metric

tensor are:

$$g_{11} = g_{22} = g_{33} = 1, \quad g_{44} = -c^2(1 + gx/c^2)^2, \tag{8.5.3}$$

and all other are zero. In the $x\tau$-direction, the contracted Ricci tensor vanishes, because each of the components, $R_{11} = R_{44} = 0$, and so too does the Gaussian curvature [cf. Sec. 9.10.3 for details].

It is one thing to assume that gravity propagates at the speed of light, but another to assume that it travels at $c(1+gx/c^2)$ [Møller 52, p. 257], which is what (8.5.3) claims. Thus, the Euler–Lagrange equations (8.5.2) reduce to a single equation,

$$\frac{d^2x}{d\tau^2} = \frac{1}{2}\frac{\partial g_{44}}{dx}\left(\frac{dt}{d\tau}\right)^2 = -g\left(1 + gx/c^2\right)\left(\frac{dt}{d\tau}\right)^2, \tag{8.5.4}$$

where $i = 1$ and $k = l = 4$. The increment in proper time is related to coordinate time by [Møller 52, p. 247]

$$d\tau = dt\sqrt{\left(1 + \frac{2}{c^2}\chi - \frac{u^2}{c^2}\right)}, \tag{8.5.5}$$

where

$$\chi = gx\left(1 + \frac{gx}{2c^2}\right),$$

is the so-called scalar gravitational potential [Møller 52, p. 255], and $u = |dx/dt|$ is the speed of the particle measured from the rest frame.

If we use coordinate time, the equation of motion (8.5.4), with the help of (8.5.5), becomes

$$\frac{d^2x}{dt^2} - \frac{2g/c^2}{1 + gx/c^2}\left(\frac{dx}{dt}\right)^2 + g(1 + gx/c^2) = 0.$$

The solution to this equation,

$$x = \frac{c^2}{g}\left[\left(1 + \frac{gx_0}{c^2}\right)\operatorname{sech}(gt/c) - 1\right], \tag{8.5.6}$$

for the initial conditions $x = x_0$, and $dx/dt = 0$, clashes with (4.3.37), which, in the present case, is

$$x = \frac{c^2}{g}\left(\cosh\frac{g\tau}{c} - 1\right).$$

In fact, differentiating with respect to proper time gives

$$\frac{d^2x}{d\tau^2} = g\cosh(g\tau/c) = \frac{d\chi}{dx} = g(1 + gx/c^2), \tag{8.5.7}$$

which is simply Newton's second law!

There is no *physical* reason why the speed,

$$u = |dx/dt| = c(1 + gx_0/c^2)\tanh(gt/c)\mathrm{sech}(gt/c),$$

should show a maximum in time when the particle is under constant acceleration, nor is there any reason to call $c\left(1 + gx/c^2\right)$ the velocity of light when it is apparent that this velocity becomes infinite as $x \to \infty$. There is also no reason to consider (8.5.5) a valid relation between proper and coordinate velocities when the particle is under acceleration. Moreover, it is also apparent from (8.5.6) that proper (hyperbolic) and coordinate times have been confused. This is evident from Møller's conclusion:

> For $t \to \infty$ the particle approaches the singular wall $x = -c^2/g$ of our system of coordinates. At this place also the velocity of light tends to zero, and no signals of any kind will ever reach the boundary plane.

Thus, general relativity has a 'black hole' at the boundary of a system in which the particle is merely undergoing uniform acceleration!

We are thus forced to conclude that the geodesic equation (8.5.2) does not fix the motion of a moving observer relative to another. By 'comoving' it is meant that the observer is at rest relative to the matter placed at his position, but the observer is allowed to move freely with no forces acting on him. This also puts into serious doubt whether the curvature of space, as contemplated from the metric tensor (8.5.1), really describes the action of gravity!

8.6 Hyperbolic Geometry of Relativity

All the relations of relativity can be derived directly from the hyperbolic differential of arc length, or the Beltrami metric, in velocity space. Consider a velocity vector with two components, u_1 and u_2. Moreover, consider a disc of radius c in which a line passing through the center is cut by another line forming an angle θ with it. The Euclidean distance from the center of the circle to the point of intersection is $u/c = \sqrt{\left(u_1^2 + u_2^2\right)}/c$. In Euclidean

space, distances are relative. Congruent triangles of different sizes can all have the same angles. No so in Lobaschevsky geometry where, as we have seen, the angles determine the sides of the triangle. Hence, lengths are also absolute.

The Euclidean length of the increment in the velocity $du = \surd(du_1^2 + du_2^2)$ will be related to the hyperbolic measure $d\bar{u}$ by

$$d\bar{u} = \Lambda\, du,$$

where

$$\Lambda = \frac{\surd(1 - u^2 \sin^2\theta/c^2)}{1 - u^2/c^2}. \tag{8.6.1}$$

From the definition of the curl,

$$\mathbf{u} \times d\mathbf{u} = u\, du \sin\theta,$$

we may write the hyperbolic line element as

$$d\bar{u} = \frac{\surd\left(du^2 - (\mathbf{u} \times d\mathbf{u})^2/c^2\right)}{1 - u^2/c^2}, \tag{8.6.2}$$

for the hyperbolic line element in terms of $\mathbf{u}_1$ and $\mathbf{u}_2$.

Now, if $d\mathbf{u} = \mathbf{u} - \mathbf{w}$, the hyperbolic measure of their difference will be

$$\frac{\surd[(\mathbf{u} - \mathbf{w})^2 - (\mathbf{u} \times \mathbf{w})^2/c^2]}{1 - \mathbf{u} \cdot (\mathbf{w} + d\mathbf{u})/c^2} = \frac{\surd[(\mathbf{u} - \mathbf{w})^2 - (\mathbf{u} \times \mathbf{w})^2/c^2]}{1 - \mathbf{u} \cdot \mathbf{w}/c^2} + O(du), \tag{8.6.3}$$

on the strength of (8.6.2), where $O(du)$ is an infinitesimally small quantity of than higher order than

$$\surd[(\mathbf{u} - \mathbf{w})^2 - (\mathbf{u} \times \mathbf{w})^2/c^2].$$

If the two velocity vectors are parallel, (8.6.3) reduces to (6.3.1). If not,

the composition of Lorentz transforms in different directions involve rotations, as Einstein knew in 1905.

If we want to determine the hyperbolic length between $\mathbf{u}_2$ and $\mathbf{u}_1$, we write the velocity vector in parametric form

$$\mathbf{u} = \mathbf{u}_1 + \lambda(t)(\mathbf{u}_2 - \mathbf{u}_1) \qquad 0 \le \lambda(t) \le 1,$$

and introduce it into the expression [Fock 69]

$$\bar{u} = \int_0^1 \frac{\sqrt{(\dot{u}^2 - (\mathbf{u} \times \dot{\mathbf{u}})^2/c^2)}}{1 - u^2/c^2} dt,$$

to get

$$\bar{u} = c \int_0^1 \frac{\sqrt{[(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2/c^2]}}{1 - u^2/c^2} d\lambda. \tag{8.6.4}$$

If we set

$$\lambda = \frac{(c^2 - u^2)}{2a} \ln\left(\frac{b + ax}{b - ax}\right),$$

where the constants

$$a = \sqrt{(c^2(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2)},$$

and

$$b = c^2 - \mathbf{u}_1 \cdot \mathbf{u}_2,$$

the integral (8.6.4) becomes

$$\bar{u} = c \int_0^1 \frac{ab\, dx}{b^2 - a^2x^2} = \frac{c}{2} \ln\left(\frac{b + a}{b - a}\right), \tag{8.6.5}$$

which is the hyperbolic measure of distance.

Using the well-known relation for inverse hyperbolic functions, (8.6.5) can be written as

$$\frac{a}{b} = \tanh(\bar{u}/c). \tag{8.6.6}$$

Squaring both sides of (8.6.6) and multiplying by c^2,

$$\frac{(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2/c^2}{(1 - \mathbf{u}_1 \cdot \mathbf{u}_2/c^2)^2} = c^2 \tanh^2(\bar{u}/c),$$

shows that the left side of (8.6.6) is the ratio of the relative velocity to c. Whereas the Euclidean measure of the relative velocity is bounded from above by c, there is no limit on its hyperbolic measure $\bar{u}$.

To see the relation between the hyperbolic measure of distance, (8.6.5), and the Lobaschevskian arc length, (8.6.2), we write the former in the form

$$\bar{u} = \frac{c}{2} \ln \left[1 + \frac{2\sqrt{[c^2(\mathbf{u}_2^2 - \mathbf{u}_1^2) - (\mathbf{u}_1 \times \mathbf{u}_2)^2]}}{c^2 - \mathbf{u}_1 \cdot \mathbf{u}_2 - \sqrt{[c^2(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2]}} \right].$$

Considering the second term in the argument of the logarithm as small, we approximate $\ln(1+x) \simeq x$ so that

$$\begin{aligned} \bar{u} &= c \frac{\sqrt{\left[c^2(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2\right]}}{c^2 - \mathbf{u}_1 \cdot \mathbf{u}_2 - \sqrt{\left[c^2(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2\right]}} \\ &\simeq \frac{\sqrt{\left[(\mathbf{u}_2 - \mathbf{u}_1)^2 - (\mathbf{u}_1 \times \mathbf{u}_2)^2/c^2\right]}}{1 - \mathbf{u}_1 \cdot \mathbf{u}_2/c^2} + O(|\mathbf{u}_2 - \mathbf{u}_1|), \end{aligned} \tag{8.6.7}$$

where the remainder in (8.6.7) contains higher-order terms in the velocity difference. In the case of parallel vectors, (8.6.7) reduces to the velocity composition law, (6.3.1).

If we specialize to the case of parallel vectors, (8.6.5) reduces to

$$\begin{aligned} \bar{u} &= \frac{c}{2} \ln \left(\frac{c^2 - u_1 \cdot u_2 + c(u_2 - u_1)}{c^2 - u_1 \cdot u_2 - c(u_2 - u_1)} \right) \\ &= \frac{c}{2} \ln \left(\frac{c - u_1}{c - u_2} \cdot \frac{c + u_2}{c + u_1} \right) \\ &= \frac{c}{2} \ln \{u_2, u_1 | -c, c\}. \end{aligned} \tag{8.6.8}$$

The argument of the logarithm is our old friend the cross-ratio, and underscores its fundamental role in defining distance in hyperbolic space. This shows that the Lobaschevsky segment is really the shortest distance between two points on the hyperbolic plane.

We recall from Sec. 2.2.4 that projections are transformations that change lengths and angles. No property of three points can be invariant because any three points can be transformed into any other three points on the line. Four collinear points are needed $(c, u_2, u_1, -c)$ for the cross-ratio (8.6.8). Connecting these points by lines emanating from a common point, the invariance of the cross-ratio can be shown as an invariance of the ratio of the angle formed from this vertex, as we have done in Sec. 2.2.4.

As u_2 moves toward c, the cross-ratio, as well as its logarithm, increases indefinitely. Rather, if u_2 is found between u_1 and $-c$, the cross-ratio will be

between 0 and 1. This makes the hyperbolic distance (8.6.8) negative. And as u_2 moves along the line toward $-c$, the hyperbolic length will decrease indefinitely. Hence, the points $\pm c$ are 'infinitely distant.' Infinitely distant points are upper and lower bounds on the Euclidean measures of distance, in this case velocities, since we are working in velocity space. The same can be said about configuration space, where the points at infinity will be given by $\pm c/\omega$, with the frequency to be defined, for example, in considering gravitational collapse, whose free-fall frequency is $\omega = \sqrt{(G\rho)}$, where G is the Newtonian gravitational constant and ρ is the density of matter.

We can also write the hyperbolic distance (8.6.8) as

$$\bar{u} = \frac{c}{2} \ln \left(\frac{1}{c-u} \cdot \frac{c+u}{1} \right), \tag{8.6.9}$$

by setting $u_1 = 0$ and putting $u_2 = u$. Alternatively, we can equate (8.6.9) with (8.6.8) without any prior conditions and find the velocity subtraction law,

$$u = \frac{u_2 - u_1}{1 - u_1 \cdot u_2/c^2}. \tag{8.6.10}$$

The subtraction, and not the addition, law for velocities is required for the construction of the cross-ratio.

It is also quite remarkable that the triangle defect of hyperbolic geometry corresponds exactly with the angle of aberration. When a moving object, like us who are on Earth, is trying to determine the position of another object, say a star, the directions to the star will differ by aberration. That is, consider an incoming ray in the xy-plane. With respect to two platforms S and S' moving at a relative velocity v with respect to one another, an incoming light signal will make angles α and α', respectively.

The velocity components in the x and y directions will be related by

$$u'_x = \frac{u_x - v}{1 - u_x v/c^2} \quad \text{and} \quad u'_y = \frac{u_y}{\gamma(1 - u_x v/c^2)}.$$

The velocity components of the incoming light signal will be $u_x = -\cos\alpha$ and $u_y = -c\sin\alpha$, with analogous expressions in the primed platform. Hence, the formulas for aberration are [cf. (8.3.6)]

$$\cos\alpha' = \frac{\cos\alpha + v/c}{1 + (v/c)\cos\alpha}, \tag{8.6.11a}$$

and [cf. (8.3.9)]

$$\sin\alpha' = \frac{\sin\alpha}{\gamma(1+(v/c)\cos\alpha)}. \tag{8.6.11b}$$

With the aid of the half-angle formula,

$$\tan\frac{1}{2}\alpha' = \frac{\sin\alpha'}{1+\cos\alpha'},$$

the formulas for aberration, (8.6.11a) and (8.6.11b) can be combined to yield [cf. (8.3.17)]

$$\tan\frac{1}{2}\alpha' = K\tan\frac{1}{2}\alpha. \tag{8.6.12}$$

Consider two types of displacements from $\mathbf{u}$, $d\mathbf{u}$ and $\delta\mathbf{u}$, where

$$d\bar{u}^2 = c^2\frac{c^2(d\mathbf{u})^2 - (\mathbf{u}\times d\mathbf{u})^2}{(c^2-u^2)^2},$$

and

$$\delta\bar{u}^2 = c^2\frac{c^2(\delta\mathbf{u})^2 - (\mathbf{u}\times \delta\mathbf{u})^2}{(c^2-u^2)^2}.$$

By the definition of the cosine of the angle between the two displacements [Fock 69],

$$d\bar{u}\cdot\delta\bar{u} = d\bar{u}\,\delta\bar{u}\cos\alpha = c^2\frac{c^2du\cdot\delta u - (u\times du)\cdot(u\times\delta u)}{(c^2-u^2)^2},$$

we have

$$\cos\alpha = \frac{c^2d\mathbf{u}\cdot\delta\mathbf{u} - (\mathbf{u}\times d\mathbf{u})\cdot(\mathbf{u}\times\delta\mathbf{u})}{\sqrt{\left[c^2(d\mathbf{u})^2-(\mathbf{u}\times d\mathbf{u})^2\right]}\cdot\sqrt{\left[c^2(\delta\mathbf{u})^2-(\mathbf{u}\times\delta\mathbf{u})^2\right]}}, \tag{8.6.13}$$

as the expression for the cosine of the angle between the relative velocities of two bodies.

8.7 Coordinates in the Hyperbolic Plane

Consider an orthogonal system through the origin O in Fig. 8.5. Let U and P be the points on the axes where the perpendicular projections from a point P not lying on the axes meet the axes. We then have a Lambert quadrilateral $\square OVPU$. If the angle at P were a right angle, we would have Euclidean geometry; if it is acute we have hyperbolic geometry.

Fig. 8.5. A Lambert quadrilateral in velocity space consisting of three right-angles and one acute angle.

Though named after Lambert, it was known to Ibn al-Haytham almost seven hundred years earlier [Rosenfeld 88]. This is yet another example of Stigler's law of eponymy.

The distances to the points U and V are

$$\bar{u} = \tanh^{-1} u, \quad \text{and} \quad \bar{v} = \tanh^{-1} v. \tag{8.7.1}$$

The Weierstrass coordinates can now be introduced as

$$X = \bar{u}T, \quad Y = \bar{v}T, \quad \text{and} \quad T = \cosh \bar{u} \cosh \bar{w}, \tag{8.7.2}$$

where $\bar{u}$, $\bar{v}$ $\bar{w}$, and $\bar{z}$ are four sides of a Lambert quadrilateral, shown in Fig. 8.5, consisting of three right angles and one acute angle between $\bar{w}$ and $\bar{z}$.

The condition that the two sides will intersect to form an acute angle is

$$1 - \tanh^2 \bar{u} - \tanh^2 \bar{v} = 1 - u^2 - v^2 > 0. \tag{8.7.3}$$

The Euclidean measures of the two sides are

$$w = \frac{u}{\sqrt{(1 - v^2)}} = \tanh \bar{u} \cosh \bar{v},$$
$$z = \frac{v}{\sqrt{(1 - u^2)}} = \tanh \bar{v} \cosh \bar{u}.$$

By giving to each point the triple (X, Y, T) of Weierstrass coordinates, the hyperbolic plane is mapped onto the locus

$$T^2 - X^2 - Y^2 = 1,$$

which is one of two sheets of a hyperboloid in Cartesian three-dimensions.

The infinitesimal metric,

$$\begin{aligned} d\bar{\sigma}^2 &= dX^2 + dY^2 - dT^2 = d\bar{w}^2 + \cosh^2 \bar{w}\, d\bar{u}^2 \\ &= \frac{(1 - v^2)du^2 + 2uv\, du\, dv + (1 - u^2)dv^2}{(1 - u^2 - v^2)^2}, \end{aligned} \tag{8.7.4}$$

is the spatial component of the Lobaschevsky velocity space metric. If we want a full time-velocity space metric we must magnify the T coordinate, $t^r > 0$ times, viz. $T = t^r/\sqrt{(1 - u^2 - v^2)}$. This results in a time-like, indefinite metric,

$$d\tau^2 = dT^2 - dX^2 - dY^2 = dt^{r\,2} - t^{r\,2} d\bar{\sigma}^2, \tag{8.7.5}$$

which we will meet again in our discussion of cosmological models in Sec. 9.11.

A time-velocity metric, similar to (8.7.5), was derived by Friedmann in 1922 using the Einstein equations to relate the coordinates to the Lagrangian variables, u_i. It was derived under the condition that matter was 'dust-like' exerting zero pressure, which is certainly a dubious assumption and does not correspond to anything physical. It was also assumed that the velocities variables u_i are constants relating the spatial coordinates x_i to time, but, subsequently, they were differentiated to obtain the Lobaschevsky–Friedmann metric (8.7.5) [Fock 69].

As can be seen from the definition of the Weierstrass coordinates, (8.7.2), each of the coordinates become magnified t^r times [Fock 69, Eq. (94.47)]. In a multi-dimensional velocity space, the spatial part of the metric (8.7.4) can be written as

$$d\bar{\sigma}^2 = \frac{(d\mathbf{u})^2 - (\mathbf{u} \times d\mathbf{u})^2}{(1 - \mathrm{u}^2 - \mathrm{v}^2)^2},$$

by introducing the coordinates $X_i = u_i t^r/\sqrt{(1-u^2-v^2)}$ into the infinitesimal metric,

$$d\bar{\tau}^2 = dT^2 - \sum_i X_i^2.$$

In relation to the Robertson–Walker metric, which we will come across in Sec. 9.11, the scale factor $R(t)$ multiplying the spatial part of the metric is just t, which implies uniform expansion. Introducing logarithmic, or hyperbolic, time according to

$$\bar{t} = t_0 \ln (t^r/t_0), \tag{8.7.6}$$

where t_0 is the age of the system on the t^r scale, (and not (8.4.30)) into (8.7.5) gives

$$d\bar{\tau}^2 = e^{2\bar{t}/t_0}\{d\bar{t}^2 - t_0^2(d\bar{w}^2 + \cosh^2 \bar{w}\, du^2)\}. \tag{8.7.7}$$

The proper time interval is the quantity $\bar{\tau}_0$ determined at constant velocity by the equation

$$\bar{\tau}_0 = \int_0^{\bar{t}} e^{t/t_0} dt = t_0 \left(e^{\bar{t}/t_0} - 1\right).$$

This law could have been anticipated because t^r is the geometric mean. Only for $\bar{t} \ll t_0$ will the proper time coincide with $\bar{t}$. The exponential variable scale factor multiplies both time and velocity increments, and testifies to the fact that they are not independent, but, are related by the Beltrami coordinates and logarithmic time.

For fixed t_0 the velocity space line element is

$$d\bar{\sigma}^2 = t_0^2 e^{2\bar{t}/t_0}(d\bar{w}^2 + \cosh^2 \bar{w}\, d\bar{u}^2). \tag{8.7.8}$$

The terms in the parentheses have the metric form of a pseudosphere in velocity space, with constant negative curvature, -1, that we introduced in Sec. 2.5 and met on many an occasion. The scale factor is the same exponential that appears in the proper time increment. The hallmark of a pseudosphere is that lines which do not intersect are, nevertheless, not parallel. Along a light track (8.7.7) vanishes resulting in

$$d\bar{t} = t_0 \frac{\sqrt{\left[(1-u^2)^2 dw^2 + (1-w^2) du^2\right]}}{(1-u^2)(1-w^2)}.$$

This is a generalization of the well-known one-dimensional expression, whose integral identifies (8.2.1) as the length of the corresponding segment of a Lobaschevsky straight line.

8.8 Limiting Case of a Lambert Quadrilateral: Uniform Acceleration

A limiting case arises when inequality (8.7.3) reduces to an equality

$$u^2 + v^2 = 1, \tag{8.8.1}$$

or $v = \sqrt{(1 - u^2)} =: u^*$. The velocities $\bar{u}$ and u^* are said to be complementary [Greenberg 93]. The defining relation for uniform acceleration is (8.4.16), which upon resolving for the velocity gives

$$u = \tanh \bar{u} = \frac{2(r/t)}{1 + (r/t)^2}. \tag{8.8.2}$$

r/t represents the Euclidean 'length,' while $\bar{u}$ is the length that Poincaré used; the two being related by

$$\mathrm{e}^{\bar{u}} = \frac{1 + (r/t)}{1 - (r/t)}. \tag{8.8.3}$$

The complementary velocity is found to be

$$u^* = \frac{1 - (r/t)^2}{1 + (r/t)^2} = \operatorname{sech} \bar{u} = \sqrt{(1 - u^2)},$$

which verifies (8.8.1).

The angle of parallelism, (8.2.10),

$$\Pi(\bar{u}^*) = 2 \tan^{-1} \mathrm{e}^{-\bar{u}^*}, \tag{8.8.4}$$

is defined solely in terms of the 'distance' $\bar{u}^*$ from the foot of the perpendicular to the angle of parallelism. The angle of parallelism is the lower bound for the angle of parallax.

It was Bernoulli who first showed that

$$2 \tan^{-1} \mathrm{e}^{-\bar{u}^*} = \frac{1}{\mathrm{i}} \ln \left(\frac{1 + \mathrm{i}\mathrm{e}^{-\bar{u}^*}}{1 - \mathrm{i}\mathrm{e}^{-\bar{u}^*}} \right). \tag{8.8.5}$$

This is because

$$\Pi(\bar{u}^*) = \frac{2}{\mathrm{i}} \tanh^{-1}\left(\mathrm{i}\mathrm{e}^{-\bar{u}^*}\right),$$

which is equal to (8.8.4).

In particular,

$$r/t = \tanh \bar{u}/2 = \tan \Pi(\bar{u}^*)/2 = \mathrm{e}^{-\bar{u}^*} \tag{8.8.6}$$

shows that the closer the complementary velocity u^* is to zero, the closer Π is to being a right angle. For large u^*, or nonrelativistic velocities, the angle of parallelism is practically zero. For the Earth's orbital motion, (8.8.6) is 10^{-4}, giving an angle of parallelism $\Pi = 89^0 59' 39.4''$. The deviation from Euclidean space is only $20.6''$. However, things change drastically as the velocity of light is approached: for a relative velocity 0.95, the angle of parallelism drops to $18^0 12'$, and vanishes in the limit [Silberstein 14].

The double angle formula,

$$\begin{aligned} \tan \Pi(\bar{u}^*) &= \frac{\mathrm{e}^{-\bar{u}^*} + \mathrm{e}^{-\bar{u}^*}}{1 - \mathrm{e}^{-2\bar{u}^*}} \\ &= 1/\sinh \bar{u}^* = \sinh \bar{u}, \end{aligned} \tag{8.8.7}$$

shows that Π provides the link between circular and hyperbolic functions. In particular, (8.8.7) relates the angle of parallelism to the particle velocity.

Consider a Lambert quadrilateral with three right angles and an ideal point in Fig. 8.6. Equation (8.8.7) implies that the complementary velocities,

Fig. 8.6. A Lambert quadrilateral comprised of complementary segments where the 'fourth vertex' is an ideal point.

$\bar{u}$ and $\bar{u}^*$, which are adjacent to the two angles of parallelism, are related by

$$\begin{aligned} e^{\bar{u}^*} &= \frac{1+\cosh\bar{u}}{\sinh\bar{u}} = \coth\bar{u}/2 \\ &= \left(\frac{1+e^{-\bar{u}}}{1-e^{-\bar{u}}}\right), \end{aligned} \tag{8.8.8}$$

and an identical expression for $\bar{u}$ in terms of $\bar{u}^*$. Equation (8.8.3) implies the addition law for the hyperbolic measure of the complementary velocities, which, in turn, implies the product law for the average velocities.

Rather, if $\bar{u}_1$ and $\bar{u}_2$ are the components of the hyperbolic measure of the velocity $\bar{u}$, their composition law follows velocity composition law:

$$e^{-\bar{u}} = \frac{e^{-\bar{u}_1} + e^{-\bar{u}_2}}{1 + e^{-\bar{u}_1-\bar{u}_2}}. \tag{8.8.9}$$

Finally, the generalization of (8.8.6) to n components,

$$\prod_{i=1}^{n} \tan\left[\Pi(\bar{u}_i^*)/2\right] = e^{-\sum_{i=1}^{n}\bar{u}_i^*} = G^n = \tanh(\bar{u}/2), \tag{8.8.10}$$

selects out the geometric mean $G = (e^{\bar{u}_1^*}e^{\bar{u}_2^*}\cdots e^{\bar{u}_n^*})^{1/n}$, and the last equality follows from (8.8.8), which is valid for a single complementary velocity or a sum of n velocities.

The opposite right angle is divided into two angles of parallelism such that

$$\Pi(\bar{u}) + \Pi(\bar{u}^*) = \pi/2. \tag{8.8.11}$$

8.9 Additivity of the Recession and Distance in Hubble's Law

The fact that the shift $z = \delta\lambda/\lambda_0$ for lines in the spectrum of a given galaxy is independent of the wavelength is a necessary, but not a sufficient condition, that the redshift is due to motion. It was Edwin Hubble who interpreted these redshifts as Doppler shifts, which are indicative of recessional motion. In so doing he obtained a linear relation between the velocity of recession, $\bar{u}$, and radial distance, r, with a constant of proportionality that is the same for all galaxies. We will show that both these quantities are *additive*.

There will be a redshift if the detected wavelength, λ, is greater than the emitted wavelength, λ_0, in

$$1 + z = \frac{\lambda}{\lambda_0} = K = e^{\bar{u}}. \tag{8.9.1}$$

Now, K is the ratio of the received, t_2, to the emitted time, t_1. We can therefore define a hyperbolic measure of the time interval as [Milne 48]

$$\bar{t}/t_0 = \ln \frac{t_2}{t_1} = \ln K. \tag{8.9.2}$$

A comparison of (8.9.1) and (8.9.2) results in

$$\bar{u} = \bar{t}/t_0 = H\bar{r}, \tag{8.9.3}$$

where $\bar{u}$ is the hyperbolic measure of the velocity, $H = t_0^{-1}$, the Hubble parameter, and $\bar{r} = \bar{t}$ is the hyperbolic measure of distance in natural units. Hubble's law (8.9.3) could have also been derived by setting the one-dimensional velocity space metric (8.4.29) equal to zero, and introducing the logarithmic time (8.7.6).

Consequently, (8.9.1) is the exponential law [Prohovnik 67]

$$1 + z = e^{H\bar{t}}. \tag{8.9.4}$$

Only when $H\bar{t} \ll 1$ can we neglect powers of $H\bar{t}$ greater than first so that (8.9.4) reduces to the relation [Hoyle *et al.* 00]

$$z = H\bar{t}. \tag{8.9.5}$$

The exponential law (8.9.4) implies that when there are more than one redshifts, it is their geometric mean which should be taken. For example, the cluster Group II has $n = 21$ redshifts, in which case (8.9.1) generalizes to

$$\prod_{i=1}^{n}(1 + z_i) = \prod_{i=1}^{n}\frac{\lambda_i}{\lambda_{0i}} = \prod_{i=1}^{n}K(\bar{u}_i) = \exp\left(\sum_{i=1}^{n}\bar{u}_i\right). \tag{8.9.6}$$

Hyperbolic velocities, $\bar{u}_i$, like the hyperbolic distances $\bar{r}_i$, are therefore additive. The average wavelength is the geometric mean wavelength. This is implied by the exponential law (8.9.6).

Chapter 3
Thermodynamics in a Carnot Equation

3.1 Why Exterior Differentials?

Because of the nonconservative nature of thermodynamic fields, exterior differential forms seem like the natural formulation of thermodynamics. The so-called covectors of heat and work, $\mathcal{H}$ and $\mathcal{F}$, are not gradients of any scalar functions. Information can be had by studying their "curls," which are nonvanishing and measuring the deviations of these functions from "gradients," which would lead to state functions that are path independent. These equations can be considered as being analogous to the first and second laws of circuitation in electrodynamics (Heaviside 1893).

A great simplification is that the usual state space of thermodynamics is the plane in which the "cross product" or "wedge product," $\wedge$, of covectors in the state plane can be interpreted as a vector pointing in the direction "perpendicular" to the plane (Hannay 2006). The resulting "covector," which is not an arrow vector because directions and distances are not defined in thermodynamics, is "perpendicular" to the state plane, which can be treated, therefore, like a scalar quantity.

Let us briefly review some elementary notions of differential forms. 0-forms are scalars, like $f = f(x^1, x^2)$. 1-forms, or linear forms, like $A_1 \mathrm{d}x^1 + A_2 \mathrm{d}x^2$, are also known as Pfaffians. And to complete the list we will have need of the 2-form, $B_{12} \mathrm{d}x^1 \wedge \mathrm{d}x^2$. A natural question is why the "wedge," $\wedge$? (Flanders 1963). Naturally, we would like to integrate the 1- and 2-forms, which are the familiar line, $\int_{\mathcal{C}} A_1 \mathrm{d}x^1 + A_2 \mathrm{d}x^2$, and surface, $\iint_{\mathcal{A}} B_{12} \mathrm{d}x^1 \wedge \mathrm{d}x^2$, integrals, respectively. These integrals are "oriented" integrals in the sense that the curve $\mathcal{C}$ in the line integral has a sense of direction and that the surface $\mathcal{A}$ has an "outward" normal to it. Reversing the normal changes the sign of the integral.

In addition, we want a rule for a change of variables, which is given by the Jacobian transformation

$$\mathrm{d}x^1 \wedge \mathrm{d}x^2 = \frac{\partial(x^1, x^2)}{\partial(y^1, y^2)} \mathrm{d}y^1 \wedge \mathrm{d}y^2.$$

Interchanging rows in the Jacobian changes the sign of the Jacobian, and, consequently, we must have $\mathrm{d}x^2 \wedge \mathrm{d}x^1 = -\mathrm{d}x^1 \wedge \mathrm{d}x^2$, if the transformation of variables

ment which will slowly subside if the piston-rods be free; or, if a be fixed, a pressure at a will be gradually brought on by the slow leakage from A to B, so that a second sudden motion of the piston back to its proper zero can be got on unfixing a. (Remove the battery, but close the circuit still; the first discharge will approximately equal the first charge, but there is left a small charge which will slowly subside if the circuit remain closed; or, if it be insulated, a difference of potential of the same kind as before will gradually come on, so that a second discharge can be got on again closing the circuit.)

To instantly remove the displacement of the piston after leakage has occurred, we must apply an opposite force, a pressure at b or pull at a of the right amount to bring the piston to the middle. If we then fix a and leave the thing to itself the pressure of the rod at b will gradually subside. Similarly if we, after absorption has occurred in a condenser, and the first discharge has been taken, charge it oppositely by a reverse E.M.F. of the right amount to make the real displacement zero, and leave the condenser insulated, the apparent opposite charge will gradually disappear.

Since the first discharge equals the first charge we may regard the capacity of the condenser as being constant, and the displacement at any moment to consist of two parts, first that due to the battery E.M.F., which can be got rid of at any moment, and next a temporary intrinsic displacement which is kept up by impressed electric force in the dielectric itself arising from its altered structure, or the changed zero of its elastic deformation. The displacement due to a certain total E.M.F. in the circuit is the same however it be distributed, whether in the conductor or dielectric, if, over any cross-section, it be evenly distributed. But only the part in the conductor causes difference of potential in a steady state between the ends of the conductor, so that the intrinsic displacement due to internal impressed force gives no external sign of its existence until, by the removal of the impressed force, difference of potential is developed between the terminals of the condenser.

In the case of the piston in the cylinder, the intrinsic force keeping up displacement of the piston after the rods have been set free is the pressure of air in A against the piston from left to right, which, had it not been for the leakage, would have been in B, and have pressed the piston the other way.

Another effect may be mentioned. If the dielectric of the condenser be of a such a nature that its capacity increases or decreases with the temperature, then, on suddenly charging it, there will be a cooling or a heating effect produced in the dielectric. This has also its parallels in the metal spring and "spring of the air" illustrations.

Intrinsic displacement in a dielectric, without conducting matter surrounding it, to render the displacement wholly latent, has also some interesting features, which will be considered later.

SECTION XI. THE PRINCIPLE OF THERMAL RESISTANCE.

Suppose we, with a sure faith in the truth of the principle of Conservation of Energy, and a knowledge of the equivalence of work and heat,

Digitized by Microsoft®

observe that the motion of a magnet in the neighbourhood of a closed circuit generates heat in it, that this ceases when the motion ceases, and that we satisfy ourselves that this heat is the only final result of the motion, so far as energy is concerned. This heat must be the equivalent of work done. As we have no reason to suppose that the magnet is in a different state at the end from what it was in at the beginning of the motion, we cannot attribute the heat to a loss of potential energy by the magnet. Hence we may conclude that the heat is the equivalent of work done against resistance to the motion of the magnet. That is to say, however the magnet move, its motion is resisted. Here we have Lenz's law, without any reference to the direction of the current induced in the circuit, but merely as regards conservation. In fact we made no mention of current. If now we bring in other knowledge, that there is a current induced in the circuit, the heat being proportional to the square of its strength, we are still left without means of determining its direction in a given case. Only finally, when we utilise Ampère's determination of the mutual forces between magnets and currents, can we exactly say in which direction the induced current will be in a given case, for it must always be such as to resist the motion.

Lenz's law is not, however, the subject of the present section, but is used to point out the distinction between the above kind of resistance to motion and the kind involved in the Principle of Thermal Resistance, to which we now proceed. It is such a large subject, and there are so many ways of treating it, that it is difficult to know how to begin; after consideration I adopt a method which I have not met with, and which is therefore, if not novel, at least unusual; believing that, whether it be better or worse than other methods, there is advantage in viewing a truth from all possible sides, to allow another law, that of the survival of the fittest, which, like that of thermal resistance, results from averages, to have a chance of operating.

We cannot, in general, alter the configuration of a body without doing work upon it, or letting the body do work. Considering any solid elastic body, for example, a straight wire: we cannot twist it without doing work. The motion is therefore resisted. On the other hand, if we let the wire untwist, it can do work itself against external resistance. Here, of course, we must have conservation of energy when all actions are taken into account, and nothing novel, so far, is presented. But there is, during the changes of configuration of an elastic body, another kind of resistance brought into play, depending upon the rate of change of configuration, at least, usually. Suppose we twist a wire slowly, and at every stage of the process note exactly the amount of the applied force, or do the same by small instalments. By summation we know the total work done in producing a given twist. Similarly, if we let the wire untwist slowly by small instalments, the force will be the same in the same configuration as during the twisting, and the same amount of work will be done by the body. But if we twist the wire *suddenly* to the same extent as before, *more* work will have to be done, or there will be an additional resistance to the motion at every moment; and if

Digitized by Microsoft®

the wire suddenly untwist, it will do *less* work, or again, there is a resistance to the motion which did not exist before.

We may put it this way: If we measure statically the forces in different configurations we do not by summation get the total work done. There is always an additional resistance to the motion, opposing the change of configuration, never assisting it. I call this thermal resistance, because, whenever it occurs, there is a thermal effect also produced. It is not, however, necessarily a heating, as one might expect, but may be either a heating or a cooling. But, whichever it be, the change of configuration is always resisted. That is the cardinal fact that must be remembered.

If, during the change of configuration, the body be allowed to part with or to receive heat so as to neutralise the thermal effect if it be a heating or a cooling respectively (as by conducting the operation very slowly, and not thermally insulating the body), the thermal resistance itself is evanescent. On the other hand, if the body be thermally insulated, so that heat cannot leave or enter it, it will be of the full amount. This will serve to elucidate the effect above mentioned of *suddenly* changing the configuration. We then give no time for heat to escape or be taken in appreciably. Now given this law, or principle of thermal resistance, and a statement of one effect upon a body, deduce another. I give a few examples.

(1). We observe that heat lengthens and cold shortens a bar. What should be the thermal effect of suddenly stretching it? It must be such as to oppose the stretching; that is, to shorten the bar, and is therefore a cooling.

(2). What should be the effect of removing the stretching force? To oppose the return to the unstretched length, therefore to lengthen the bar; therefore a heating.

(3). Water above 4° C. expands by heating, what is the effect of compression? Such as to oppose the compression; therefore a heating.

(Notice there are two effects—the thermal resistance and the heating or cooling effect.)

(4). Water below 4° C. contracts by heating. The effect of compression is, therefore, to cool it, as the compression is thereby resisted.

(5). Water expands in vaporising. Hence pressure raises the boiling point.

(6). Water expands in freezing. Hence pressure lowers the freezing point.

(7). An india-rubber band at ordinary temperatures, stretched by a weight, lifts it when heated. What should result from suddenly stretching the band? The motion must be resisted; that is the invariable fact. The thermal effect is therefore a heating, for that, by the previous, lifts a weight.

(8). A twisted wire is suddenly twisted further. Is it a heating or a cooling effect that is produced? Whichever it be, it must increase the torsional rigidity, so as to oppose the twisting. If, then, heat lessens the torsional rigidity, it is a cooling effect, and conversely.

(9). Compressing a gas heats it. Hence heat applied to a gas increases its pressure, for this is the only way to make the compression be addi-

Digitized by Microsoft®

tionally resisted. This property of a gas is so well known that it is more difficult to recognise the principle. It is hard to imagine the possibility of a gas being cooled by compression. Yet the principle involved is identically the same as in the less obvious illustrations.

Other mechanical illustrations may be multiplied indefinitely, but the above will be sufficient. When we wish to go further, and make applications to electricity or magnetism, it is necessary to be very particular that the necessary conditions are complied with. The thermal resisting force is always opposed to the motion, and so far resembles a frictional force; but the thermal effect, unlike that of friction, is reversible with the direction of motion, and the motion produced by heat is reversed if cold be applied. Thus, during the stretching of a spring, the pull of the spring is $F+f$, if F be what it would be if there were no thermal effect, and f is the small increase produced by, or accompanying it. On the other hand, when the spring shortens, the strength of force is $F-f$ at a corresponding stage, and at the same temperature, f being the same quantity as before. Regarding the forces as vectors, **F** is constant in direction, **f** changes, being with **F** in the stretching, and against it in the unstretching. That is, it is always against the direction of motion. The heat effect, if it be a cooling during the stretching, is a heating during the unstretching. And as regards the effect of heat, if heating increases, cooling must decrease the elasticity. If in some peculiar state, both heating and cooling produced the same effect on the elasticity, or if either stretching or unstretching produced the same thermal effect, we could not immediately apply the principle without reservation. Further investigation would be needed.

(10). Given a circuit of two metals A and B, at one temperature initially. We observe that slightly heating one junction causes a current from A to B, and cooling it causes a current from B to A. Here is a perfectly reversible thermal effect, although accompanied by other strictly irreversible effects in the circuit. In accordance with the principle, what should be the thermal effect at the same junction on passing a current from an external source from A to B? The current must be made weaker than it would otherwise be, hence the current due to the thermal effect is from B to A, hence it is a cooling, by the previous knowledge. At the other junction it must be a heating, for the current is there from A to B. Thus there is a transfer of heat from the first junction to the second. Notice the peculiarity that the thermoelectric force in the circuit, due to both junctions, weakens the main current; that is the first conclusion. But the E.M.F. at both junctions is from A to B, whence it follows that at the first junction the E.M.F. is weaker than at the second. Further inquiries would lead us to the full theory of thermoelectricity. [*See* pp. 309 to 327.]

(11). Given that the capacity of a condenser is increased by heating and decreased by cooling the dielectric, what should be the thermal effect of suddenly charging it? The charging must be opposed, hence a decrease of capacity or a cooling effect. Similarly, suddenly discharging the condenser should produce a heating effect, which we may conclude thus:—The discharge must be resisted. Now, the rate

Digitized by Microsoft®

of discharge depends upon the difference of potential of the ends of the discharge wire. This must be reduced, therefore. But a reduction of potential with the same charge means an increase of capacity, for which there must be, by the above, a heating effect. Observe here that these thermal effects are independent of the absorption phenomenon.

(12). A curious result of thermal resistance is that a perfectly elastic solid, if such really existed, vibrating, would come to rest without any external or internal friction to cause it. Thus in a vibrating spring, thermal resistance opposes its motion whether it be moving to or from the equilibrium position. Now, if the spring could give out and take in heat instantaneously, so as to keep its temperature constant, the effect would vanish, and, without friction, the spring go on for ever. Similarly, if the spring could be thermally insulated, the cooling and heating effects produced when moving to or from the equilibrium position would balance, and the spring could go on for ever. But practically, neither one nor the other condition can be complied with, and the spring must be brought to rest without friction entirely by the thermal effect being practically radiated or conducted away in one motion, without an exactly counterbalancing receipt of heat in the opposite motion.

There is another way of looking at the principle which is useful, viz., to direct attention to the flow of heat into or out of the body when it is being strained, supposing that the body is, in the first place, in thermal equilibrium with its environment, and that it can receive or lose heat instantaneously. Thus, in example (9), compressing a gas drives heat out of it. Now, go to the other end of the operation. Take heat out of a gas. It compresses itself. Or take example (1). Stretching a bar draws heat into it, and sending heat into a bar makes it stretch itself. From this point of view we regard two events as being invariably connected—motion of matter of a certain type, and a flow of heat in a certain way. But the method is less general than the preceding, assuming, as it does, that the flow of heat is always permitted, likewise the motion.

In all cases whatever in which the principle of thermal resistance has been experimentally tested, it has been found to be correctly followed by Nature. Can we then assert its invariable truth, and apply the principle unhesitatingly to hitherto unverified cases, possibly unverifiable? Is it possible to give a rigid demonstration of its truth? The first question may [within certain limits] be answered in the affirmative, the latter not. We cannot prove it even as we prove the truth of conservation of energy, viz., by seeing that it is a necessary truth in pure dynamics, and extending our notions to all the operations of nature; observing that it is experimentally true in a great many cases, and convincing ourselves of its universal application with the assistance of a little faith. For we cannot deduce the principle of thermal resistance from the laws of dynamics. It would be no breach of conservation of energy were it to be exactly reversed, were strains to be assisted by thermal effects. All we can really do is to convince ourselves that, being true in all observed cases, and its negation leading to extra-

Digitized by Microsoft®

ordinary consequences which are *not* observed, though not dynamically impossible *à priori*, it must, by faith, be generally true.

First, put the principle in a mathematical form. Let an elastic body be strained from one configuration to another, keeping it always at one temperature t, to allow which a quantity of heat H leaves the body, whilst W is the work done upon the body. Then the principle asserts simply that $dW/dt \div H$ is positive, or that dW/dt and H are either both positive or both negative, which is easily verified by the above examples. More work is caused to be done by the thermal effect if it be not than if it be allowed to escape.

Next, to see the consequences of its negation, follow the example of the founder of thermodynamics, Sadi Carnot, when, in the most masterly and scientific manner, he set to work to find the cause of the motive power of heat. After the above strain, bring the body back exactly to its original state through the same series of intermediate configurations, but at a slightly different temperature $t+dt$. This requires there to be two other operations (2nd and 4th), viz., to raise the temperature by dt in the second configuration, and to lower it by dt when it has got back to the first. Now the body does work $W+(dW/dt)dt$ at the higher temperature. Hence, in the complete cycle, the body does work $(dW/dt)dt$. What else happens is that an amount of heat H is lowered in temperature by the amount dt. Now, without any experience to guide us, H and dW/dt may be algebraically positive or negative, and not of the same sign necessarily. But if they could be of opposite signs, work would be obtained through a substance *raising* the temperature of heat. If then we take it as axiomatic that it is impossible by conveying heat from a cold to a hot body to obtain mechanical effect, then we prove that the law of thermal resistance is universally true, at least for bodies in mass, and inanimate.

Now this axiom, so called, is really the principle Carnot was led to, viz., work is derived from heat by *lowering* its temperature. Carnot's principle is thus a consequence of the principle of thermal resistance. In Carnot's cycle for a gas engine heat is taken in at a higher and given out at a lower temperature, and the pressure is greater at the higher than at the lower, so that the gas does more work in expanding than is done in compressing it back to its original state, and thus we have finally heat lowered in temperature, and work done by the gas. In his water and vapour cycle it is similar, so he concluded that the necessary condition of obtaining work by thermal agency was the lowering the temperature of heat. He was only wrong as regards the *quantity* of heat lowered in temperature.

Now this being a consequence of the principle of thermal resistance, and the various examples above given being commonly regarded as consequences of the Second Law of Thermodynamics, with which Carnot was most assuredly not acquainted, how is it that Carnot was acquainted with *them?* I do not say he thought of them all. But he knew some of them, and, had he been asked what would be the result in a given case, according to his principle, he would have given the correct answer. Only his reason for the answer would have been erroneous. For the

Digitized by Microsoft®

only legitimate reason that Carnot could have for applying his principle universally would be that he had proved that all reversible engines had the same efficiency between the same temperatures, so that his principle, known to be true for one body, must be true for all.

But this proof was vitiated by his erroneous assumption of the materiality of heat, then universally believed in, and was only put right long after, by Clausius and Thomson, on the basis of the equivalence of heat and work, fully established experimentally by Joule. Carnot founded his proof on a perfectly unexceptionable axiom (on his view of the nature of heat). Work could be obtained without any thermal agency if all reversible engines had not the same efficiency between the same temperatures. The substituted axioms of Clausius and Thomson are by no means so satisfying, considered as axioms. They express truths, they involve Carnot's principle, they involve the principle from which Carnot's is derived, but they are not axioms, unless a law of Nature, only to be learnt by experience, is an axiom.

Clausius said that heat will not pass from cold to hot by itself, or without compensation. True enough, by definition of cold and hot, if the cold and hot bodies be in contact. Otherwise not self-evidently true, though a law of Nature. Thomson said we cannot get work out of a body by cooling it below the lowest temperature of surrounding objects. This I also admit to be true, knowing that it involves Carnot's principle, and believing that; but it is not self-evidently true. A third axiom that can be used is that we cannot convert heat into work without lowering the temperature of heat. This I believe to be the best of all, being the simplest expression of the truth of Carnot's principle that work is got by lowering the temperature of heat.

Of course Carnot was wrong in his quantitative estimate of the efficiency of reversible engines, but his principle remains unaltered. When, with the principle of thermal resistance, we combine that of the equivalence of work and heat, and use Carnot's criterion of the perfectness of an engine, that it must be reversible, we arrive at an absolute measure of temperature independent of any particular substance, and using it, give quantitative expression to the principle of thermal resistance, viz. :—

$$dW/dt = H/t,$$

where t is temperature according to the scale of equal dilatations of an imaginary perfect gas under constant pressure, whose energy, at constant temperature, is independent of its volume. It now becomes a form of the Second Law of Thermodynamics.

There is a reason for everything, and therefore (if that be an axiom) for the axioms of thermodynamics, better called laws. The reason of conservation of energy the student of dynamics can understand, if he can grant that the laws of matter in motion observed in masses are true for the smallest parts of bodies. The reason of thermal resistance is also, by the aid of the kinetic theory of gases, becoming evident, and will no doubt some day be established for all bodies. It arises from the irregular nature of the motions we call heat. We cannot control single molecules. Could we do so, down would go the law of thermal resist-

Digitized by Microsoft®

ance and heat could be converted straight into work, molecular irregular motions to an equivalent amount of motion of a mass, the irregularity disappearing, without at the same time having to lower the temperature of another quantity of heat, as at present required. But what we cannot do with inanimate matter may be going on always to a certain extent in living matter; not because living matter is exempt from any law of Nature, but that we do not yet know all its laws. The perpetual running down of the available energy of the universe is a matter that must be cleared up. It is incredible that it can always have been going on, and dismal in its final result if uninterrupted. It is therefore the duty of every thermodynamician to look out for a way of escape.

Section XII. Electrization and Electrification. Natural Electrets.

A dielectric, not including ether, the universal medium, when under the influence of electric force, may be said to become electrized. We must not say electrified, as that refers to something entirely different from electrization, namely, electrification, or discontinuity in the displacement. The proper measure of the intensity of electrization will appear presently; in the meantime we need only observe that electrization is the analogue of magnetization, and, like it, requires the presence of matter.

Electrization may be approximately perfectly elastic with reference to the standard zero state, as in a dielectric in which absorption does not occur, so as to disappear on the removal of the exciting cause. This must be an impressed electric force somewhere, except in a transient inductive state, when there may be none, unless we choose to consider the electric force of induction as impressed; or else there must be electrification somewhere. There may also be residual electrization, namely, when absorption occurs. This may tend naturally to wholly subside, or a part of it may remain. The body is then permanently electrized. But, apart from artificial production of permanent electrization, it exists naturally in pyro-electric crystals, if nowhere else.

A word is evidently wanted to describe a body which is naturally permanently electrized by internal causes. Noticing that "magnet" is got from "magnetism" by curtailment at the third joint from the end, it is suggested that we may get what we want by performing the same operation upon electricity. An "electric," which is what results, would be a very good name for an intrinsically electrized body, but for two reasons. First, it was once used to signify what we should now call a dielectric or an insulator; and secondly, electric is now used as an adjective, or, equivalently, electrical. The former of these objections is of hardly any weight, that use of the word as a substantive being wholly obsolete. The latter is heavier, but still of no great importance. Another word that suggests itself is electret, against which there is nothing to be said except that it sounds strange. That is, however, a mere question of habit. Choosing, at least provisionally, the second

Pág. 33-36

the inductivity of a medium to that of ether, which is, in fact, consistent with the original meaning, I believe, as used by Sir W. Thomson in connection with his "electromagnetic definition" of magnetic force. But to inductivity, as beforementioned, a wider significance should be attached. As has been more particularly accentuated by Prof. Rücker, we really do not know anything about the real dimensions of μ and c; or, more strictly, we do not know the real nature of the electromagnetic mechanism, so that μ and c are very much what we choose to make them, by assumptions. The two principal systems are the so-called electrostatic, in which $c=1$ in ether, and the electromagnetic, in which $\mu=1$ in ether. But with these specialities we have no further concern at present.

Cross-connections of Electric and Magnetic Force. Circuital Flux. Circuitation.

§ 33. The two sets of quantities, the electric and magnetic forces, with their corresponding fluxes and currents, and the connected products and ratios, may be considered quite independently of one another, without any explicit connection being stated between the electric set and the magnetic set, whether they coexist or not. But to have a dynamical electromagnetic theory, we require to know something more, viz., the cross-connections or interactions between **E** and **H**. Or, in another form, we require to know how an electric field and a magnetic field mutually influence one another.

One of these interactions has been already partially mentioned, though only incidentally, in stating the meanings of permeance and inductance. It was observed that the electric current in a simple conductive circuit was measured by the gaussage in the corresponding magnetic circuit.

A word has been much wanted to express in a convenient and concise manner the property possessed by some fluxes and other vectors of being distributed in closed circuits. This want has been recently supplied by Sir W. Thomson's introduction of the word "circuital" for the purpose.* Thus electric current is a circuital flux, and so is magnetic induction. The fundamental basis of the property is that as much of a circuital flux enters

* "Mathematical and Physical Papers," Vol. III., p. 451.

any volume at some parts of its surface as leaves it at others, so that the flux has no divergence anywhere. This qualification, "anywhere," should be remembered, for a flux which may diverge locally, as, for instance, electric displacement, is not circuital in general, though even electric displacement may be circuital sometimes. Further, as a flux need not be distributed throughout a volume, but may be confined to a surface, or to a line, we have then specialised meanings of circuital and of divergence. Or a volume-distribution and a surface or line-distribution of a flux may be necessarily conjoined, without, however, any departure from the essential principle concerned.

The word "circuital," which will be often used, suggested to me the word "circuitation," to indicate the often-occurring operation of a line-integral in a closed circuit; as, for instance, in the estimation of circuital voltage or gaussage. Now, in the case of a moving fluid, Sir W. Thomson called the line-integral of the velocity in a closed circuit the "circulation." This is curiously like "circuitation." But "circulation" seems to have too specialised a meaning to be suitable for application to any vector, and I shall employ "circuitation." The operation of circuitation is applicable to any vector, whether it be circuital or not.

First Law of Circuitation.

§ 34. Now in the case of a simple conductive circuit, we have two circuital fluxes. There is a circuital conducting core supporting an electric current, and there is a circuital flux of induction through the conductive circuit. In the electric circuit we have Ohm's law,

$$E = RC, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where E is the circuital voltage, C the current, and R the resistance. And in the magnetic circuit we have a formally similar relation,

$$H = L^{-1}B, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where H is the circuital gaussage, B the induction, and L^{-1} the reluctance. Or,

$$B = LH, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where L is the inductance (or the permeance, when there is only one turn of wire).

Now, the cross-connection in this special case is implied in the assertion that H and C are the same quantity, when measured in rational units The expression of the law of which this is an illustration is contained in any of the following alternative statements.

The line-integral of the magnetic force in any closed circuit measures the electric current through any surface bounded by the circuit. Or,

The circuitation of the magnetic force measures the electric current through the circuit. Or,

The electric current is measured by the magnetic circuitation, or by the circuital gaussage.

The terminology of electromagnetism is in a transitional state at present, owing to the change that is taking place in popular ideas concerning electricity, and the unsuitability of the old terminology, founded upon the fluidity of electricity, for a comprehensive view of electromagnetism. This is the excuse for so many new words and forms of expression. Some of them may find permanent acceptation.

The above law applies to any circuit of any size or shape, and irrespective of the kind of matter it passes through, meaning by "circuit" merely a closed line, along which the gaussage is reckoned. By "the current" is to be understood *the* current; not merely the conduction current alone, or the displacement current alone, but their sum (the convection current term will be considered separately).

It is also necessary to understand that a certain convention is implied in the statement of the law, regarding positive senses of translation and rotation when taking line and surface integrals. Look at the face of a watch, and imagine its circumference to be the electric circuit. The ends of the pointers travel in this circuit in the positive sense, if you are looking through the circuit along its axis in the positive sense. Also, you are looking at the negative side of the circuit. Thus, when the current is positive in its circuit, the magnetic induction goes through it in the positive direction, from the negative side to the positive side. Otherwise, the positive sense of the current in a circuit and the induction through it are connected in the same way as the motions of rotation and translation of a nut on an ordinary right-handed screw. This is the "vine" system used

by all British writers; but some continental writers use the "hop" system, in which the rotation is the other way, for the same translation. It is useless trying to work both systems, and when one comes across the left-handed system in papers, it is, perhaps, best to marginally put the matter straight, and then ignore the text.

Second Law of Circuitation.

§ 35. The other cross-connection required is a precisely similar relation between voltage and magnetic current, with, however, a change of sign. Thus :—

The negative line-integral of the electric force in any circuit (or the electric circuitation) measures the magnetic current through the circuit. Or,

The voltage in any circuit measures the magnetic current through the circuit taken negatively. Or,

Magnetic current is measured by the circuital voltage reversed; and other alternative equivalent statements.

Definition of Curl.

§ 36. In the above laws of circuitation the currents are the concrete currents (surface-integrals), and the forces also the concrete voltage or gaussage. When we pass to the unit volume it is the current-density that is the flux. The circuitation of the force is then called its "curl." Thus, if $\mathbf{J}$ be the electric current and $\mathbf{G}$ the magnetic current, the two laws are

$$\text{curl } \mathbf{H}_1 = \mathbf{J}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

$$-\text{curl } \mathbf{E}_1 = \mathbf{G}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where $\mathbf{E}_1$ and $\mathbf{H}_1$ are the electric and magnetic force of the field. We may now say concisely that

The electric current is the curl of the magnetic force.

The magnetic current is the negative curl of the electric force.

There is nothing transcendental about "curl." Any man who understands the laws of circuitation also understands what "curl" means, though he may not himself be aware of his knowledge, being like the Frenchman who talked prose for many years without knowing it. The concrete circuitation is sufficient for many problems, especially those concerning linear

conductors in magnetic theory. But it does not suffice for mathematical analysis, and to go into detail we require to pass from the concrete to the specific and use curl. How to manipulate "curl" is a different matter altogether from clearly understanding what it means and the part it plays. The latter is open to everybody; for the former, vector-analysis is most suitable.

Let a unit area be chosen perpendicular to the electric current **J**. Its edge is then the circuit to which $\mathbf{H}_1$ belongs in (4). The gaussage in this circuit measures the current-density. Similarly, regarding (5), the voltage in a unit circuit perpendicular to the magnetic current measures its density (negatively). In short, what circuitation is in general, curl is the same per unit area.

Impressed Force and Activity.

§ 37. In the statement of the laws of circuitation, I have intentionally omitted all reference to impressed forces. That there must be impressed forces is obvious enough, because a dynamical system comprehending only the electric and magnetic stored energies and the Joulean waste, is only a part of the dynamical system of Nature. We require means of showing the communication of energy to or from our electromagnetic system without having to enlarge it by making it a portion of a more complex system. Thus, taking it as it stands at present, the activity per unit volume we have seen to be

$$\mathbf{EJ} + \mathbf{HG} = Q + \dot{U} + \dot{T}, \quad . \quad . \quad . \quad . \quad . \quad (6)$$

where the left side expresses the activity of the electric and the magnetic force on the corresponding currents, and the right side what results, viz., waste of energy, Q per second, and increase per second of the electric energy U and the magnetic T; and, as there are supposed to be no impressed forces, if we integrate through all space, we shall obtain

$$0 = \Sigma\,(Q + \dot{U} + \dot{T}), \quad . \quad . \quad . \quad . \quad . \quad (7)$$

where Σ means summation of what follows it. Or, if Q_0 be the total waste, and similarly U_0 and T_0 the total energies,

$$0 = Q_0 + \dot{U}_0 + \dot{T}_0,$$

meaning, that whatever energy there be wasting itself is derived solely from the electric or magnetic energy, which decrease accordingly. This is the persistence of energy when there are no impressed forces.

Now, if there be impressed forces communicating energy at the rate A, the last equation must become

$$\Sigma \mathbf{fv} = A = Q_0 + \dot{U}_0 + \dot{T}_0, \quad . \quad . \quad . \quad . \quad (8)$$

and A must be the sum of the activities of the impressed forces **f** in the elements of volume, in whatever way space may be divided into elements, large or small, and however we may choose to reckon the impressed forces. There may be many ways of doing it; **f** may sometimes, for example, be an ordinary force, and **v**, the velocity to match, is then a translational velocity. But for our immediate purpose, it is naturally convenient to reckon the impressed forces electrically and magnetically; so that the corresponding velocities are the electric and magnetic currents. We shall then have, if **e** be the impressed electric, and **h** the impressed magnetic force,

$$\mathbf{eJ} + \mathbf{hG}$$

to represent their activity per unit volume, and in all space,

$$\Sigma (\mathbf{eJ} + \mathbf{hG}) = \Sigma (Q + \dot{U} + \dot{T}) \quad . \quad . \quad . \quad (9)$$

instead of (7). This is the integral equation of activity. We cannot remove the sign of summation and make the same form do for the unit volume, for this would make every unit volume independent of the rest, and do away with all mutual action between contiguous elements and transfer of energy between them. This matter will be returned to in connection with the transference of energy.

Distinction between Force of the Field and Force of the Flux.

§ 38. The distinction between $\mathbf{H}_1$ and **H** and between $\mathbf{E}_1$ and **E** is often a matter of considerable importance. We have

$$\mathbf{H} = \mathbf{h} + \mathbf{H}_1, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

$$\mathbf{E} = \mathbf{e} + \mathbf{E}_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

Now it is **E** and **H** that are effective in producing fluxes. Thus **E** is the force of the flux **D** and also of **C**; and **H** is the force of the flux **B**. On the other hand, in the laws of circuitation, as above expressed, the impressed forces do not count at all; so that we have, in terms of the forces **E** and **H**,

$$\text{curl}\,(\mathbf{H}-\mathbf{h})=\mathbf{J}, \quad . \quad . \quad . \quad . \quad . \quad (12)$$

$$-\text{curl}\,(\mathbf{E}-\mathbf{e})=\mathbf{G}, \quad . \quad . \quad . \quad . \quad . \quad (13)$$

equivalent to (4) and (5). To distinguish from the forces of the fluxes, I sometimes call $\mathbf{E}_1$ and $\mathbf{H}_1$ the forces "of the field." Of course they only differ where there is impressed force. As the distribution of the energy, as well as of the fluxes, depends upon **E** and **H**, it is usually best to use them in the formulæ.

Classification of Impressed Forces.

§ 39. The vectors representing impressed electric and magnetic force demand consideration as to the different forms they may assume. Their line-integrals are impressed voltage and gaussage. Their activities or powers are **eJ** and **hG** respectively per unit volume, and in this statement we have a sort of definition of what is to be understood by impressed force. For, **J** being the electric current anywhere, if there be an impressed force **e** acting, the amount **eJ** of energy per unit volume is communicated to, or taken in by, the electromagnetic system per second; and this should be understood to take place at the spot in question. It must then be either stored on the spot, or wasted on the spot, or be somehow transmitted away to other places, to be there stored or wasted, according to a law which will appear later on. Similarly as regards **h** and **G**.

But this concerns only the reckoning of impressed force, and is independent of its physical origin, which may be of several kinds. Thus under **e** we include—

(1.) Voltaic force.

(2.) Thermo-electric force.

(3.) The force of intrinsic electrisation.

(4.) Motional electric force.

(5.) Perhaps due to various secondary causes, especially in connection with strains.

And under **h** we include—

(1.) The force of intrinsic magnetisation.

(2.) Motional magnetic force.

(3.) Perhaps due to secondary causes.

Voltaic Force.

§ 40. Voltaic force has its origin in chemical affinity. This is still a very obscure matter. For a rational theory of Chemistry, one of the oldest of the sciences, we may have to wait long, in spite of the activity of chemical research and of the development of the suggestive periodic law. Yet Chemistry and Electricity are so intimately connected that we cannot understand either without some explanation of the other. Electricity is, in its essentials, a far simpler matter than Chemistry, and it is possible that great light may be cast upon chemical problems (and molecular physics generally) by previous discoveries and speculations in Electricity. The very abstract nature of Electricity is, in some respects, in its favour. For there is considerable truth in the remark (which, if it has not been made before, is now originated) that the more abstract a theory is, the more likely it is to be true. For example, it may be that Maxwell's theory of displacement and induction in the ether is far more than a working theory, and is something very near the truth, though we know not what displacement and induction are. But if we try to materialise the theory by inventing a special mechanism we are almost certain to go wrong, however useful the materialisation may be for certain purposes. No one knows what matter is, any more than ether. But we do know that the properties of matter are remarkably complex. It is, therefore, a real advantage to get away from matter when possible, and think of something far more simple and uniform in its properties. We should rather explain matter in terms of ether, than go the other way to work.

However this be, we have the fact that definite chemical changes involve definite voltages, and herein lies one of the most important sources of electric current. Furthermore, there is the remarkable connection between the quantity of matter and the time-integral of the current (or quantity of electricity) produced, involved in the law of electro-chemical

Pág. 47(62) - Chapter 3 - Thermodynamics in a Carnot Equation

3.1 Why Exterior Differentials?

Because of the nonconservative nature of thermodynamic fields, exterior differential forms seem like the natural formulation of thermodynamics. The so-called covectors of heat and work, H and F , are not gradients of any scalar functions. Information can be had by studying their "curls," which are nonvanishing and measuring the deviations of these functions from "gradients," which would lead to state functions that are path independent. These equations can be considered as being analogous to the first and second laws of circuitation in electrodynamics (Heaviside 1893).
A great simplification is that the usual state space of thermodynamics is the plane in which the "cross product" or "wedge product," ^ , of covectors in the state plane can be interpreted as a vector pointing in the direction "perpendicular" to the plane (Hannay 2006). The resulting "covector," which is not an arrow vector because directions and distances are not defined in thermodynamics, is "perpendicular" to the state plane, which can be treated, therefore, like a scalar quantity.

Chapter 12

Chapter 12 - Part 1

Appendix-01---20211115

Deus está no céu. 20081207 (1)

Deus nos deu o livre arbítrio
(mentre belho mestrado)

Começar o
livro como Pai-Nosso

associar
com
Dai a César o que é de César

Jesus uma crítica
pois Cristo foi
politicamente
correto à
épocas em
que viveu

Não
quis
questionar
a ordem jurídica
reinante.

esperto ou teve medo de que o povo se levantasse contra Roma

ou

expertos

teve muita experiência ao ver outros pseudo profetas serem mortos. Se ele gostasse, será morto antes de hora e não poderá divulgar a sua mensagem.

Sabe quem são os Imperadores

Constantino não publicar a divulgação de que mentira.

Então ele sabia!!! Será?

Pai-Nosso

Pai Nosso que estais nos céus

Ele está lá e não aqui. Portanto, não está por conta própria.

Ensinamentos de Jesus Cristo foi nomeado de sua consciência, mas a sua influência não que reflexos no mundo físico.

Somente no mundo pós-morte e para aqueles que acreditam, os homens mais puros.

O homem que não aceita o que é proposto, não poderá ser punido por Deus, pois Ele ~~deu~~ deu ao homem o direito de fazer a que escolha.

Você pode fazer tudo o que quiser, melhor violar as leis de Deus, mas desde que você consiga agir dentro de uma certa legalidade e não causar prejuízo para ninguém, você não será punido neste mundo.

Isso poderá ser até desonesto e desde que você não seja pego, não lhe acontecerá nada, ou seja, use o sistema a seu favor.

Deus faz a análise dos 2 Comentários:

1 Deus provoca indireta faz com que sua vontade prevaleça neste mundo (determinismo)

2 Deus não interfere neste mundo de forma objetiva, deixando isto à critério dos homens que andam neste e que usem o seu livre-arbítrio para que sua obra seja implementada neste mundo. (misto, determinismo e livre-arbítrio)

(3) Deus não interfere em nenhuma hipótese, pois Ele estaria violando a sua própria decisão de ter dado o livre-arbítrio. Portanto, o pressuposto (premissa) que Deus nunca engana em suas decisões é verdadeiro para quem acredita.

Portanto, Deus não vai voltar atrás e fazer qualquer ingerência na tomada de decisão dos homens.

Ao interferir, Deus além de violar a sua própria decisão, estaria também interferindo em consequências que mais adiante →

a decisão de 1 pessoa e as consequências em um sistema fechado e causal.

↓

Abordar o princípio de

Causa e Efeito,

O Homem pensa que é livre, mas não é.

Ele não é livre se conhecer todas as variantes do seu conceito para a validação da sua tomada de decisão.

+

Associando-se isto ao Princípio de Causa e Efeito

O Homem poderia tomar a decisão correta e que não gerasse consequências para ele se conhecesse todas as variantes que envolve o seu problema e as consequências dos atos, ou seja,

sem Deus o homem poderia ~~pomar~~ tomar as suas próprias decisões se o homem fosse onisciente (onissapiente)

Como o homem não é?

Portanto, o homem não é livre e portanto também não há livre-arbítrio.

Para a Teoria do Direito Penal → para que haja crime há a necessidade de 2 fatores:

1) nexo de causa e efeito +

2) consciência da ilicitude

(T. clássica)

↳ mytrab ver.

Como o homem não tem consciência de seus atos, não há que se falar em culpabilidade do homem

O homem quando age não age com a consciência completa de seus atos e de seus consequências.

As consequências sempre existem pois o homem age por ação ou omissão e desta forma, atua no mundo físico

Precisamos entender a presença de Deus em nosso mundo e em nossos nós.

Deus é um elemento a mais em nossa vida para que possamos fazer uma avaliação crítica de nosso mundo.

A sua importância vai depender da interpretação pessoal de cada um e que muitos chamam de fé.

O homem pode ter fé em vários coisas ou idéias concretas como Deus, mas se a sua avaliação foi correta ou não só será somente ao próprio autor da sua própria vida, pois se há um pseudo-humanismo, não há que se falar em

acerto ou erro, pois
desde que use a própria idéia
de Jesus Cristo de que
devemos dar a César o que
é de César, portanto devemos
cumprir as leis dos homens
e portanto, o acerto ou o erro
será como parâmetro as
próprias limitações impostas
pelo próprio homem e
seu sistema jurídico.

Desta forma o enfoque
ético e moral será observado
e quantificado se estiverem
nosso sistema jurídico e
nos ter nada a ver com
a discussão da existência
ou não de Deus.

Quero acreditar na
ajuda de Deus em
minha vida.
Deus pode mudar a
mente de uma pessoa
para me ajudar ou
não me prejudicar.
Eu preciso desta ajuda quando
eu cometo um erro ~~no~~
dentro do sistema jurídico
vigente, mas se eu sempre
agir corretamente não precisarei
deste auxílio, mas para tanto
devo ter a total consciência de
minhas ações e conseqüências.
Agindo errado, precisarei
entrar na igreja religiosa e
esperar que eu seja merecedor
da graça de Deus me ajudar.

A questão é:

O livro é que leva ao homem conhecer a realidade de Deus? (A)

A verdade é que impede que o homem seja punido, mesmo que Deus não queira, pois Ele não pode violar a sua própria lei-sabe.

Verdade absoluta — Deus ou não (dentro do sistema jurídico)

Verdade relativa → dentro dos deuses dos homens, pois o homem não tem plena consciência.

(A) O erro de uma pessoa será avaliado por Deus com base nos bons atos realizados pelo infrator da Lei de Deus.

Espero que sim!!!

Ou

pedir auxílio à Deus é uma questão que ajuda o homem a superar as limitações do próprio homem, negação de alterar a sua propriedade.

Ou

serve como um meio para proteger a sua própria consciência, ou seja, cometer um erro e não consegue conviver com isto.

Será capaz de conviver com isto?

(15)

Depende
- valores morais
- valores éticos
- consciência

→ o que é a consciência?

Conhecimento da
Verdade de seus
atos.
(Vig. T. Clássico)

Pedindo à Deus que ajude a escapar de planeta de seu erro, o homem está pretendo a que consciência ou reconhecendo a sua real limitação quanto ao

entendimento do
mundo em
que vive.

O que é o erro?
Alguns pensadores indianos
sustentam a idéia de que
você é escravo do aquilo
que deseja, medita ou
faz.
Pelo menos você deseja,
menos sofrerá neste
mundo e aqui vida
humana é muito fugaz.
Desejando e agindo, você comete
erros e portanto, será punido.
Só não erra que não tenta.
A inação é um bom
negócio?

B) Verdade

A verdade tem 2 lados:

1) A verdade é sempre a verdade. Portanto, é imutável.

Jesus disse:

A verdade vos libertará.

De qual liberdade Ele falava?

a) Verdade sobre Deus < existe ou não existe

b) Verdade sobre o homem

c) Verdade sobre o que é a vida

Portanto, você agindo dentro da verdade, você não será punido pelo homem e nem por Deus.

2| A verdade é dura para aquele que erra.

↳ não aja para não errar, pois errando você terá que suportar o peso da verdade e a vergonha de ter errado, pois nós homens achamos que somos certos. Já?

Segundo conceito, você não terá que enfrentar a verdade. É mais fácil ser amigo dela do que encará-la face-a-face.

Adoro esta frase que eu criei:

O homem é punido por agir, pois o seu agir pode estar errado e portanto será punido.

O que é o mesmo?

Errar pouco durante a vida ou não agir.

Só temos uma chance.

Não agindo, não erraremos.

Agindo, você poderá errar.

O erro não é perdoado.

Se você tem medo da punição, está na caja.

Que dilema cruel!!!

Não sou o dono
da verdade e não
quero ser, mas
sou amigo dela.

OBS. Este meu posicionamento
foi tomado por amor à
verdade ou por medo de
encará-la e sofrer
as consequências do meu
erro.

Sou realmente
consciente dos muitos
~~anos~~ e amigos ou ajo por
medo de sofrer nesta
mundo?

Qual a solução?

A criação do seu próprio Estado no Império dos homens.

adequação do seu sistema político para as suas próprias realidades

incluso ou não de Deus em sua vida

evitar punição consciência dos seus atos

objetivando ter total controle sobre sua vida e das variantes envolvidas

ou

→ materializar a presença de Deus com base na fé.

usar o Estado como meio para alcançar os seus objetivos.

Usar os meus livros:

- Lógica (raciocínio)
- Falácia
- Silogismos
- Psicologia Criminal
- Livro Português sobre acesso.

Usar o texto do meu mestrado.

---

colação de grau
e
pós-graduação.

A pena de morte em um Estado, serve para que?

1. mostrar sua força soberana.
2. expurgar opositores de forma legal
3. pôr medo nos outros pessoas para que obedeçam o sistema vigente

↓

sistema panóptico

obs. fala sobre a internet e sistema de vigilância eletrônica

↓

4º Poder organizacional →

Livro de Kenneth Galbraith (23)

+

Estado Novo (livro)

(4) A defesa da ordem e a proibição da pena de morte tem por objetivos a preservação da mão-de-obra do país, obrigando e gente a trabalhos forçados.

Ou

A proibição da pena de morte é mais barato do que conduzi-lo à morte e a observância de todas as instâncias legais.

e não respeito às leis divinas.

Livro de Kenneth Galbraith (23)

+

Estado Novo (livro)

(4) A defesa da ordem e a proibição da pena de morte tem por objetivos a preservação do mito-de-obra do país, obrigando e gravo a trabalhos forçados.

Ou

A proibição da pena de morte é mais barato do que condená-lo à morte e a observância de todos os instâncias legais e não respeito às leis divinas.

Forma soberana

→ Estado laico

→ Estado religioso.

Qual é melhor?

Sistema baseado na legitimidade divina.

↓

evitar contestações dos súditos.

Ex: Faraó.

Conveniente? Sim.

Importante:

Livro legitimação pelo procedimento.

Soberania é o contínuo exercício do seu direito de tomar conta do que é seu.

Conquistado de forma legítima ou não. Basta que você tenha força para mantê-la.

Pela legitimação pelo procedimento as suas ações se materializam e se distribuem por meio de suas ações reiteradas e voltadas para o seu fim, ter soberania e mantê-la em suas mãos.

Cuidado com tratados.

Os tratados nada mais fizeram do que limitar a liberdade como governante.

Não adianta mais do que conquistar, pois voltar a depender dos outros é realmente humilhante, portanto lute pela liberdade de ação e de consciência.

O governante tem que exercer o seu poder em sua plenitude e sem limitações para que possa ser realmente livre. Seja Deus pelo menos em seu país.

The corner angles of a triangle always add up to a straight line

The corner angles of a triangle always make a straight line, no matter what kind of triangle is it.

Angles on a straight line always add up to 180°, so the corner angles of a triangle must always add up to 180°, too.

Ex:

$78 + 67 + 35 = 180$

Análise:

(Analisar)

2.1

Lembrese.

2, 4, 6, 8 → pode-se usá-los nos múltiplos

Fazer padronização

Obs. Não esqueça, simplifique ao máximo.

Não crie regras demasiadamente.

Podemos usar os 2 casos em hipóteses extremas, objetivando a solução dos problemas mais complexos.

Podemos usar o valor máximo
um valor mínimo
Não é preciso saber demonstrar
Obs: Não é preciso saber demonstrar
as afirmações, mas
conhecer o valor máximo
e o valor mínimo
Exemplo: $f(x) = x^2 - 2x$

$f(x) = x^2 - 2x$

$f(4) = 4^2 - 2 \cdot 4 = 16 - 8 = 8$

$f(5) = 5^2 - 2 \cdot 5 = 25 - 10 = 15$

$f(4) + f(5) = 8 + 15 = 23$

$f(4) + f(5) = \text{SUM}(4,5) = 23$

$f(4) + f(5) = \text{SUM}(4,5) = 23$

$f(4) + f(5) = \text{SUM}(4,5)

ou

6 + 6

(Analisar)

(important)

20110913 Pág. 21

- $8 - 3\frac{1}{7} = 8 - \frac{22}{7} = \frac{56}{7} - \frac{22}{7} = \frac{34}{7} = 4$ (important)

A) $\frac{12}{18} = \frac{12:6}{18:6} = \frac{2}{3}$

B) $\frac{3}{4} + \frac{5}{4} + \frac{7}{4} + \frac{9}{4} = \frac{3+5+7+9}{4} = \frac{24}{4} = 6$

$\frac{2}{7} + \frac{3}{7} + \frac{4}{7} + \frac{5}{7} = \frac{2+3+4+5}{7} = \frac{14}{7} = 2$

C) $5 \cdot \frac{1}{3} = \frac{5}{3} = 1\frac{2}{3}$

$\frac{5}{7} \cdot 14 = \frac{5 \cdot 14^{2}}{7 \cdot 1} = 10$

use múltiplos do denominador para multiplicar.

$\frac{5}{9} \cdot 63 = \frac{5 \cdot 63^{7}}{9 \cdot 1} = 35$

Desta forma, você obterá um número inteiro

D) $7\frac{1}{2} \cdot 3\frac{1}{3} = \frac{15}{2} \cdot \frac{10}{3} = 25$

$8 \cdot \frac{3}{4} \cdot 12 = \frac{35}{4} \cdot \frac{12^{3}}{1} = 105$

$\frac{5}{9} \cdot 63 = \frac{5}{9} \cdot \frac{63^{7}}{1} = 35$

$15 \cdot 3\frac{4}{15} = \frac{15}{1} \cdot \frac{49}{15} = 49$

$\frac{12}{18} = \frac{12:6}{18:6} = \frac{2}{3}$

b) $\frac{3}{4} + \frac{5}{4} + \frac{7}{4} + \frac{9}{4} = \frac{3+5+7+9}{4} = \frac{24}{4} = 6$

$\frac{2}{7} + \frac{3}{7} + \frac{4}{7} + \frac{5}{7} = \frac{2+3+4+5}{7} = \frac{14}{7} = 2$

c) $5 \cdot \frac{1}{3} = \frac{5}{3} = 1\frac{2}{3}$

$\frac{5}{7} \cdot 14 = \frac{5 \cdot 14^{2}}{7 \cdot 1} = 10$

$\frac{5}{9} \cdot 63 = \frac{5 \cdot 63^{7}}{9 \cdot 1} = 35$

use múltiplos do denominador para multiplicar. Desta forma, você obterá um número inteiro

d) $7\frac{1}{2} \cdot 3\frac{1}{3} = \frac{15}{2} \cdot \frac{10}{3} = 25$

$8\frac{3}{4} \cdot 12 = \frac{35}{4} \cdot \frac{12^{3}}{1} = 105$

$\frac{5}{9} \cdot 63 = \frac{5}{9} \cdot \frac{63^{7}}{1} = 35$

$15 \cdot 3\frac{4}{15} = \frac{15}{1} \cdot \frac{49}{15} = 49$

A) $\frac{12}{18} = \frac{12:6}{18:6} = \frac{2}{3}$

B) $\frac{3}{4} + \frac{5}{4} + \frac{7}{4} + \frac{9}{4} = \frac{3+5+7+9}{4} = \frac{24}{4} = 6$

$\frac{2}{7} + \frac{3}{7} + \frac{4}{7} + \frac{5}{7} = \frac{2+3+4+5}{7} = \frac{14}{7} = 2$

C) $5 \cdot \frac{1}{3} = \frac{5}{3} = 1\frac{2}{3}$

$\frac{5}{7} \cdot (14) = \frac{5 \cdot 14^{2}}{7 \cdot 1} = 10$

$\frac{5}{9} \cdot (63) = \frac{5 \cdot 63^{7}}{9 \cdot 1} = 35$

use múltiplos do denominador para multiplicar.

Desta forma, você obterá um número inteiro

D) $7\frac{1}{2} \cdot 3\frac{1}{3} = \frac{{}^{5}15}{2} \cdot \frac{10^{5}}{3} = 25$

$\frac{5}{9} \cdot (63) = \frac{5}{9} \cdot \frac{63^{7}}{1} = 35$

$\frac{}{4} + \frac{}{4} + \frac{}{4} + \frac{}{4}$

$$\frac{2}{7} + \frac{3}{7} + \frac{4}{7} + \frac{5}{7} = \frac{2+3+4+5}{7} = \frac{14}{7} = 2$$

(c) $5 \cdot \frac{1}{3} = \frac{5}{3} = 1\frac{2}{3}$

$$\frac{5}{7} \cdot (14) = \frac{5 \cdot \cancel{14}^{2}}{\cancel{7} \cdot 1} = 10$$

use múltiplos do denominador para multiplicar.

$$\frac{5}{9} \cdot (63) = \frac{5 \cdot \cancel{63}^{7}}{\cancel{9} \cdot 1} = 35$$

Desta forma, você obterá um número inteiro

(D) $7\frac{1}{2} \cdot 3\frac{1}{3} = \frac{\cancel{15}^{5}}{\cancel{2}} \cdot \frac{\cancel{10}^{5}}{\cancel{3}} = 25$

$$8\frac{3}{4} \cdot (12) = \frac{35}{\cancel{4}} \cdot \frac{\cancel{12}^{3}}{1} = 105$$

$$\frac{5}{9}(63) = \frac{5}{\cancel{9}} \cdot \frac{\cancel{63}^{7}}{1} = 35$$

$$15 \cdot 3\frac{4}{15} = \frac{\cancel{15}^{1}}{1} \cdot \frac{49}{\cancel{15}} = 49$$

$$66\frac{2}{3} : 100 = \frac{200}{3} : \frac{100}{1} = \frac{\overset{2}{\cancel{200}}}{3} \cdot \frac{1}{\cancel{100}} = \frac{2}{3}$$

(3)

$$66\frac{2}{3} : 100 = \frac{200}{3} : \frac{100}{1} = \frac{\overset{2}{\cancel{200}}}{3} \cdot \frac{1}{\cancel{100}} = \frac{2}{3}$$

$\therefore \tan\theta = \frac{b}{\alpha}$ (fig. 2)

20120120

(fig. 2)

ok: $\tan\theta = \frac{b}{\alpha}$

20120120

(fig. 2)

$\therefore \tan\theta = \frac{b}{c}$

fig. 2

$\tan\theta = \frac{b}{r}$

20120120.

$Q = 37.1°$
$W = 90°$
$Z =$

$q =$
$w =$
$z = 6.3$

$Z = 180° - (90° + 37.1°) = 52.9°$

Then using the tangent ratio and the cosine ratio, respectively, we can find q and w!

$\tan 37.1° = \frac{q}{z} = \frac{q}{6.3}$, or
(Q)

$q = 6.3 \tan 37.1° \approx 4.8$,

and

$\cos 37.1 = \frac{6.3}{w}$, or

$w = \frac{6.3}{\cos 37.1} \approx 7.9$

Now all six measures are known and we have solved triangle QWZ.

20120120.

$Q = 37.1°$ $\quad$ $q =$

$W = 90°$ $\quad$ $W =$

$Z =$ $\quad$ $Z = 6.3$

$Z = 180° - (90° + 37.1°) = 52.9°$

Then using the tangent ratio and the cosine ratio, respectively, we can find q and w!

$$\tan 37.1° = \frac{q}{z} = \frac{q}{6.3}, \text{ or}$$

(Q)

$$q = 6.3 \tan 37.1° \approx 4.8,$$

and

$$\cos 37.1 = \frac{6.3}{w}, \text{ or}$$

$$w = \frac{6.3}{\cos 37.1} \approx 7.9$$

Now all six measures are known and we have solved triangle QWZ.

20120120.

$Q = 37.1°$
$W = 90°$
$Z =$

$q =$
$w =$
$z = 6.3$

$Z = 180° - (90° + 37.1°) = 52.9°$

Then using the tangent ratio and the cosine ratio, respectively, we can find q and w!

$\tan 37.1° = \frac{q}{z} = \frac{q}{6.3}$, or
(Q)

$q = 6.3 \tan 37.1° \approx 4.8$,

and

$\cos 37.1 = \frac{6.3}{w}$, or

$w = \frac{6.3}{\cos 37.1} \approx 7.9$

[illegible] are known and

$z = 6.3$

$z = 180° - (90° + 37.1°) = 52.9°$

Then using the tangent ratio and the cosine ratio, respectively, we can find q and w:

$$\underset{(Q)}{\tan 37.1°} = \frac{q}{z} = \frac{q}{6.3}, \text{ or}$$

$$q = 6.3 \tan 37.1° \approx 4.8,$$

and

$$\cos 37.1 = \frac{6.3}{w}, \text{ or}$$

$$w = \frac{6.3}{\cos 37.1} \approx 7.9$$

Now all six measures are known and we have solved triangle QWZ.

As lições dos Laboratórios Bell

blog.estadão.com.br/renato-cruz/as-licoes-dos-laboratorios-bell/

No século passado, surgiram nos Laboratórios Bell invenções que mudaram o mundo, como o transistor e a fibra ótica, a telefonia celular e o satélite de comunicação, o laser e a célula solar de silício, o sistema operacional UNIX e a linguagem de programação C.

Jon Gertner, autor do livro The Idea Factory: Bell Labs and the Great Age of American Innovation, escreveu no New York Times sobre como eles conseguiram isso.

dos – laboratórios – Bell)

No século passado, surgiram nos Laboratórios Bell inventos que mudaram o mundo, como o transistor e a fibra ótica, a telefonia celular e o satélite de comunicação, o laser e a célula solar de silício, o sistema operacional UNIX e a linguagem de programação C.

Jon Gertner, autor do livro The Idea Factory: Bell Labs and the Great Age of American Innovation, escreveu no New York Times sobre como eles conseguiram isso.

Mervin Kelly, president dos Bell Labs na década de 50, defendia a necessidade não somente de atrair

muitos pessoas talentosas, mas de aproximar talentos de áreas diferentes. (2)

"Bem interiormente, os Laboratórios Bell colocavam pensadores e fazedores sob o mesmo teto", escreve Gertner.

Mesmo os teóricos tinham em vista que o conhecimento deveria se transformado em novos coisas.

Sediados em New Jersey, os laboratórios pertenciam à AT&T quando a operadora era a monopolista de pesquisa e desenvolvimento nos USA. (Hoje são o braço de pesquisa da fabricante de equipamentos Alcatel-Lucent.)

Os escritórios regionais dos Bell Labs eram instalados nas fábricas da AT&T,

Bell colocavam pensadores
sob o mesmo teto", escreveu Gertner.
Mesmo os teóricos tinham em vista
que o conhecimento deveria se transfor-
mado em novos cargos.
Sediados em New Jersey, os laboratórios
pertenciam à AT&T quando a operadora
era a monopolista de pesquisa e
desenvolvimento nos USA. (Hoje são o
braço de pesquisa da fabricante de
equipamentos Alcatel-Lucent.)
Os escritórios regionais dos Bell Labs
eram instalados nas fábricas da AT&T,
para auxiliar essa transição. Quando a manufatura passou a ser transferida
para a Ásia, nos últimos 50 anos, essa aproxi-
mação entre a fábrica e a torre de marfim
foi perdida.

outros pontos importantes, destacados por Gertner, foram a liberdade e o tempo que tinham os pesquisadores dos laboratórios: "Muito tempo — anos para perseguir o que eles sentiam ser essencial!"

O autor contrastou essa característica com a pressa de campeões do Vale do Silício, como o Google e Facebook, que até hoje se beneficiam dos inventos gaídos dos Bell Labs.

Um dos lemas do Facebook é "mova-se rapido e quebre coisas", enquanto o Google já descreveu sua filosofia como a busca de um "evangelho da velocidade"!

(A) Mudanças de paradigmas: (quebre coisas)

Polegadas → p/ Sistema Métrico Decimal

...ando de foco,

laboratórios. Mas eles sentiam ser essencial perseguir o que eles sentiam ser essencial.

20120513

C:\20120512\SI_unit\0412729504.pdf

Pag. 45 (60)

A sphere of diameter 1.241 cm has the same volume as the cube, a sphere of diameter 1.382 cm has the same superficial surface area and a sphere of diameter 1 cm has the same surface to volume ratio.

Consider a cube of side 1 cm; its volume $V = 1\ cm^3$ and its superficial surface area $S = 6\ cm^2$

d_V is the diameter of a sphere having the same volume as the cube and d_S is the diameter of a sphere having the same surface area.

$$V = \frac{\pi}{6} d_V^3 \quad \text{so that} \quad d_V = \left(\frac{6}{\pi}\right)^{1/3} = 1.241$$

$$S = \pi d_S^2 \quad \text{so that} \quad d_S = \left(\frac{6}{\pi}\right)^{1/2} = 1.382$$

$\Rightarrow$

20120513

C:\20120512\SI_unit\0412729504.pdf

Pag. 45 (60)

A sphere of diameter 1.241 cm has the same volume as the cube, a sphere of diameter 1.382 cm has the same superficial surface area and a sphere of diameter 1 cm has the same surface to volume ratio.

Consider a cube of side 1 cm; its volume $V = 1\ cm^3$ and its superficial surface area $S = 6\ cm^2$

d_V is the diameter of a sphere having the same volume as the cube and d_S is the diameter of a sphere having the same surface area.

$$V = \frac{\pi}{6} d_V^3 \quad \text{so that} \quad d_V = \left(\frac{6}{\pi}\right)^{1/3} = 1.241$$

$$S = \pi d_S^2 \quad \text{so that} \quad d_S = \left(\frac{6}{\pi}\right)^{1/2} = 1.382$$

$\Rightarrow$

20120513

The surface to volume ratio is of fundamental importance since it controls the rate at which the particle reacts with its surroundings. This given by:

$$\frac{S}{V} = \frac{\pi d_s^2}{\frac{\pi}{6} d_V^3} \quad \text{Thus} \quad \frac{S}{V} = \frac{6 d_s^2}{d_V^3}$$

i.e. $S_V = \dfrac{6}{d_{sV}}$

Hence, for a unit $d_{sV} = 1$.

20120513

The surface to volume ratio is of fundamental importance since it controls the rate at which the particle reacts with its surroundings. This given by:

$$\frac{S}{V} = \frac{\pi d_s^2}{\frac{\pi}{6} d_V^3} \quad \text{Thus} \quad \frac{S}{V} = \frac{6 d_s^2}{d_V^3}$$

i.e. $S_V = \dfrac{6}{d_{sV}}$

Hence, for a unit $d_{sV} = 1$.

Não há filosofia de
Matemática
genuina
valida desde que
ela demonstra.

monteiro-dias.com.br

Forbidden Planet

513 730 → 116

20140502

A matemática tem a sua razão enquanto a natureza humana perde a razão por causa das distrações cotidianas.

A matemática tem razão
O homem não tem razão,
apenas uma mera
ilusão

Com Deus, o homem conhecerá a verdadeira realidade e razão do amor.

20141018

Data_PC_24/20141018/Sistema de Unida

1) Esferorradiano (Steradian):
→ medida (SIU) para quantificar ângulos sólidos.
(equivalente tridimensional do radian

"o ângulo sólido subentendido no centr da esfera de raio r por uma porçã de superfície de área r^2.
Área da superfície da esfera é 4π
a esfera mede 4π esferadianos.

2) Côvado:
Côvado Real (Mahe) — 523 a 525 mm
7 palmos de 4 dígitos = 28 subdivisõe
Côvado Sumério: 518.5 mm ou 20.4 pol. (
Côvado de 30 dígitos: 1,728 cm (0.68 in)

Important:
Geômatras do Egito antigo calcularam a raiz quadrada de dois como a hipotenusa de um côvado. Essa unida bem atestada dos antigos Egípcios era conhecida como o "remen de construção

20140818

"semen de constantes" →
era usada com boa aproximação
de $2 \times \frac{20}{28} \geq \sqrt{2}$!

Obs.:

1 Mil = 25,4 μm

1 Pol (in) = 1000 mil = 2,54 cm ou 25,4 mm

3) Metro:

1/299792458 de segundo.

Segundo:

Duração 9192631770 períodos de radiação correspondente a transição entre dois níveis hiperfinos do estado fundamental do césio 133.

Ampère:

Corrente constante → 2 condutores a um metro de distância uma da outra no vácuo produz uma força de 2×10^{-7} Newton/metro

20141018!

Kelvin:
temperatura termodinâmica é 1/273,16 da temperatura termodinâmica do ponto triplo da água.

Candela:
É a intensidade luminosa, numa dada direção de uma fonte que emite uma radiação monocromática de frequência 540 x 10^12 Hertz e que tem uma intensidade radiante nessa direção de 1/683 watt por esferradiano (Steradian).

Data_PC_24/20141018/LUZ_import/

Sistema de Unidades: Wikipedia

1668 - John Wilkins (Data_PC_24/20141018/John_Wilkins) utilização do segundo como unidade básica de tempo, que o comprimento de um pêndulo com período de dois segundos fosse a unidade básica de comprimento,

20141018

Comprimento, sendo denominada "padrão" (equivalente a 994 mm) e que a base para massa seria a "centena", sendo definida como a massa de água destilada em um recipiente de um padrão crítico.

obs Como adequar este subdivisão ao plano cartesiano musical?

{{M}}

2015 08 08

(I) Preciso escolher 1, 1A ou 1B

(II) Não esqueça da 2ª etapa e desdobre o desenho (2A). (3A)
(atente-se aos ângulos retos)

(III) Após a escolha, adeque-o para a nova forma musicliana.

obs.:
Depois faça um entrecruzamento com seno, cosseno, etc..

+ Important:
Use aquelas criações antigas que continham as funções trigonométricas.

20150808

obs:

Depois, inspirá-o na circulo e faça as aproximações necessárias até completar toda a circunferência (o perímetro).

errado ao espaço faltante. Pertinente

---

obs: A função, ou melhor, a coordenada M tem que estar a 45° do x, y e do z faça o ajuste para teste.

Puxar o eixo M para o plano do eixo Z

20150808

Voltando à pag. 03

Inicialmente, vamos usar a versão 1B, porque 1B facilita a busca por números maiores e pares.

Usa o mesmo método de busca de números inteiros.

Importante:

Crie um algoritmo para calcular a área de um círculo e depois de uma esfera.

Usa o padrão:

Por enquanto:

Vejamos:

Podemos usar um outro sequenciamento de números que incluam menos números primos.

20150808

ou

forma de espelhamento por 4

↳ por cópia modular.

ou ainda

→ espelhamento por 8

facilita o estudo quando aplicado para a criação de um cilindro.

Neste aspecto observamos a união dos pontos

1 1
5 5 para a criação de um cilindro

estude depois o círculo

obs: Neste caso, observamos somente números pares neste círculo, facilitando assim, uma maior dificuldade em a questão fazer de restos

2015 08 08:

→

vamos usar a mesma configuração do plano cartesiano

Teremos:

4-2 4 1
8-3 8-4

usemos matrizes p/ cálculos facilitará as contas. Será?

Para criarmos um cilindro

1-2 1-1
5-3 5-4

estas colunas são utilizadas para posicionamento nos quadrantes

estas colunas são usadas para os cálculos.

Obs:
Vamos incluir a coordenada M.

20150808

outra forma de utilizarmos para gráficos matemáticos.

cilindro: (ex.:)

		M		
2	1		1	1
3	5		5	4

coordenada

estudar se este formato é correto.

~~2 1 M 1 1~~
~~3 5 5 4~~

como a coordenada M ficará a 45°?

utilizemos a diagonal.

será? estudar!!!

20150808.

Aprofundando:

Vejamos as diagonais da coordenada M

os pontos A, B, C e D são pontos de conexão da coordenada M

Função M:

1 6 A C
2 5 A C

1 6 B D
2 5 B D

2015 08 08

20150808:

Funções M: Detalhamento (coordenada M)

1 6 AC → M1
2 5 AC → M2
1 6 BD → M3
2 5 BD → M4

ou

A1 C6 → M1
A2 C5 → M2
B1 D6 → M3
B2 D5 → M4

20150809

ABF = 3 pontos do Δ
CDE = 3 pontos do Δ } 6 pontos

A1
A2 } 2
B1
B2 } 2
C5
C6 } 2
D5
D6 } 2
} 8 pontos

obs: Fazer uma tabela de conversão entre os vários aspectos destas formas de particionar uma área.

ABCD = 4 pontos

20150809

Obs:
Fazer as readequações das letras para que haja uma maior padronização.
Criar uma lista das anotações matemáticas criadas e adequadas à cada aspecto da teoria.

Vejamos

ALM = A1 faz diagon
ABM = A2
GHO = G6 (G antigo C
ABM = A2 → FGO = G
EFO = E1 (antigo B) diago
JKM = K6 (antigo D)
DEO = E2 (antigo B) diago
KLM = K5 (antigo D)

(1

20150809

Numeração por quadrantes

Ficamos com:

A → K

H → O

∴

AEF = A1 → diag → JKL = K6

ABE = A2 → diag → IJK = K5

HIJ = H1 → diag → ENO = O6

GHJ = H2 → diag → EFO = O5

Obs: H → antigo I

K → antigo O

O → antigo I

Como calcular a
progressão geométrica
exponencial
somente com
números

openoffice 4.1.0

$$a_n = a_1 \cdot q^{n-1}$$

n = número do termo
na sequência
a_1 = termo inicial
q = razão

obs. média geométrica

$-\frac{1}{4}$ ou: $\frac{-1}{4}$

$\frac{-1}{4} = 4^{-1}$ $(2)^{2(-1)} = 2^{-2}$

$2^{-2} \cdot 2^{9} = 2^{7} = 128$

Veja:

PG $\left(\frac{-1}{4}, \frac{1}{2}, -1, \ldots\right)$

$a_{10} = ?$

$a_1 = \frac{-1}{4}$

$q = -2$

$a_{10} = 2^{7} = 128$

PG de 6 termos

$a_1 = 1 \quad a_6 = 243$

$a_n = a_1 \cdot q^{n-1}$

$a_6 = a_1 \cdot q^5$

$243 = 1 \cdot q^5$

$q = \sqrt[5]{243}$

$q = 3$ (razão)

$q = (a_n / a_1)^{(1/n-1)}$

Fraction Continue

$$\frac{10}{7} = 1 + \frac{3}{7} = 1 + \frac{1}{\frac{7}{3}}$$

invertir

$$1 + \frac{1}{\frac{7}{3}} = 1 + \frac{1}{2 + \frac{1}{3}} =$$

$$[1, 2, 3].$$

Fais: $\frac{344}{77} = 4 + \frac{36}{77} = 4 + \frac{1}{\frac{77}{36}}$

$\Rightarrow$

$$\Rightarrow 4 + \cfrac{1}{2 + \cfrac{5}{36}} = 4 + \cfrac{1}{2 + \cfrac{1}{\cfrac{36}{5}}} =$$

$$4 + \cfrac{1}{2 + \cfrac{1}{7 + \cfrac{1}{5}}}$$

Fração finita

Forma abreviada:

$[4, 2, 7, 5]$.

<u>Obs</u>:
representação decimal 344/77 é infinita → dízima periódica
<u>então</u> na representação

na forma continuada é finita.

Assim:

Toda fração continuada finita representa um número racional.

Reciprocamente, todo número racional pode ser escrito na forma de uma fração continuada finita.

Portanto, toda fração continuada infinita é uma representação de um número irracional.

obs: $344 \div 77 = 4,\overline{467532}$

$77 \times 4 = 308$

$344 -$
308

36

off: $900 \div 36 = 25$

$\frac{36}{0,467532} =$

$77,\overline{000077}$

obs:

$1000 \div 36 = 27,\overline{7}$

Geratriz de dízima periódica

$0,777 = \frac{7}{9}$ $0,2323 = \frac{23}{99}$ } dízima simples

Dízima Composta:

$0,125252525 = \frac{125-1}{990} = \frac{124}{990}$

$0,0\overline{477} = \frac{047-04}{9900} = \frac{43}{900}$ → parte não periódica

} dízima composta

20160716:

(2)

Fração Contínua (cont.)

$$1,6\overline{4} = \frac{64-6}{90} = \frac{58}{90} = 1+\frac{58}{90} = \frac{148}{90}$$

período

devido à parte ~~não~~ do antiperíodo.

ou

$$1,6\overline{4} = \frac{164-16}{90} = \frac{148}{90}$$

(este cálculo vai direto)

Ex:

$$2,4\overline{7321} = \frac{247321-2473}{99000}$$

período

antiperíodo

Demonstração:

$x = 1,6\overline{44}$

$10x = 16,444$

$100x = 164,444$

$$100x - 10x = 164,444 - 16,444$$

$$148$$

$90x = 148$

$$x = \frac{148}{90}$$

Obs:

$1,01$ = aumento 1%

Valor $\times 1,01$ = Valor + 1%

No caso:

$1,64$

↳ só aumenta um zero na equação.

$x = 0{,}424242$ ou

$0{,}\overline{42} \times 100 =$

$x = 0{,}\overline{42}$

$100x = 42{,}\overline{42}$ −

$x = 0{,}42$

$x = \frac{42}{99} \Rightarrow x = \frac{14}{33}$

Gleason

J.S. Christopher

A circunferência foi dividida em 24 partes,

No círculo vermelho há 2 divisões:

1) Dividido por 4 (interno)

2) Dividido por 3 (externo)

A externo contém as seguintes divisões:

Cada divisão foi novamente dividida por 5 partes.

ex: 1/2/3/4/5/ e depois

Dividido por 2 e novamente por 2.

ex:

criando-se ao todo

60 partes p/ cada uma das partes do ano exemplo vermelho. ~~que também foi dividido por 3.~~

~~60 X 3 = 180~~

60 partes X 24 =
1440 partes

Ao entrar no vermelho

4 partes

$4 \times 24 = 96$ partes

Analisar

a cronicidade entre as duas escalas de duração.

(5)

A distância do círculo C no ponto I entre o círculo D no ponto R = 0,41421356237309 5 (= $\sqrt{2}$).

O ponto I é o ponto de contato entre o círculo C e o círculo P.

O círculo P tem as seguintes intersecções:

A) Ponto I no círculo C;

B) Pontos K e L no círculo E e

C) Pontos M → no eixo x
N → no eixo y } valores iguais

3,121320343559 64

20170526:

A distância $\overline{QP} = \sqrt{2} = 1.4142...$

Você usando um compasso com abertura de 1 unidade de distância, coloque-a sobre o ponto Q e risque, faça o mesmo sobre o ponto P e risque, o teremos a intersecção V e sobre este faça a bissetriz com pontos em Q e P.

Observando-se o prolongamento desta bissetriz até o eixo X, observamos que o ponto N é exatamente o ponto M + 1 unidade de distância.

Devo salientar que os dois ~~ambos~~ catetos do triângulo MZ(N)W é $1/2\sqrt{2}$ e a hipotenusa é igual 1 (unidade)

$\downarrow$

$\frac{\sqrt{2}}{2}$

Atente-se o triângulo MTS, sendo M e T os catetos cujo valor $= \sqrt{2}$ e a hipotenusa $= 2$ (MS).

O triângulo MTW(N) é 1/2 deste, o valor da hipotenusa desta está correta.

Obs: A distância entre V e Z é 1,5 unidades.

20170925 Estrelas

(1)

Hiparco 150 A.C → 6 escalas de magnitudes

Tycho Brahe

1ª Mag → 2 min de arco no céu.

Ex: Sirius

(1/15 lua tamanho da)

Sec. XIX – medir a distância das estrelas (paralax das estrelas).

1856 – Pogson (intensidades da luz. fotometria)

$m = -2.5 \log f + c$

(aparent)

f → fluxo da estrela

c → constante. (calibrar)

Vega = 0

(escala inversa)

qto > fluxo < magnitude.

ΔM

$m_1 - m_2 = -2.5 \log f_1/f_2$

(razão entre os fluxos)

→ retorna a constante de Vega

Sirius $-1,46$

$m = -1,46$

obs: Sol ⇒ $m = -27$

magnitude → aparente

cor da estrela → índice de cor.

filtros → UBV

ultravioleta, blue, visual

$B = -2.5 \log f(B) + c$

$V = -2.5 \log f(V) + c$

$B - V = -2,5 \log f(B)/f(V)$

↳ índice de cor

fotometria precisa.

2017092 5 Estrelas (2)

paralaxe. (depende da posição do observador)

Parsec - 1 second arc
3.3 anos-luz

medida de distância

(trigonométrica)

θ = paralaxe
(ângulo)

Paralaxe Trigonométrica.

$\theta = 1/2$ ângulo total.

Alfa Centauro → + prox. do Sol.
< 1 segundo arco.

1º medida → Friedrich Bessel
1ª paralaxe trigon.

→ 1.3 parsec de distância.

Magn. Absoluta: (com base 10 parsec por padrão)

relacionada com a luminosidade (intrínseca da estrela)

Prox. Centauro

	Mag (Mv)	L/Lsol
↳	15.5	6×10^{-6}

Sol =	MV	L/Lsol
(5 grandeza)	4,83	1

(à dist. de 10 parsec).

Betelgeuse =	−5,6 (Mv)	7×10^{5} L/Lsol

↳ 700.000 + luminosa que o Sol.

índice de cor também é intrínseco da estrela.

20170926

(1)

Lei de Wien: calcular temp

→ temperatura da estrela se equipara com os transições atômicas de cada átomo.

→ tipo espectral

G (= Sol)

raias atômicas

São tirados do espectro de cada estrela.

O BAFGKM (seq. de temp. das frequências espectrais).
(classificação)

Obs: índice de cor
está associado a ~~[illegible]~~ temperatura da estrela.

Azul → + quente.
Vermelho → − quente.

3 formas de medir a temperatura
- temp
- tipo espectral
- índice de cor

Dados absolutos: (intrínseco da estrela).

{ magnitude absoluta
temperatura

Luminosidade:

linhas estreitas = estrelas grandes
linhas largas = estrelas pequenas.

baixa densidade

grande densidade.

Anã marrom → queima deutério (e não hidrogênio).

20 X massa júpiter = queima deutério, mas não consegue virar estrela.
(até

75 a 80 X massa júpiter = queima Hz.

20170926

(2)

anã infravermelha → até menor
(seria o correto) usado

$M < M_s < 13$

obs: Sol ÷ 13 Jupiter × 13
(massa)

faixa das anãs menores

20170927

Diagrama HR

- Lei Stefan-Holtzman (radiação)

$4\pi R^2$ → depende fortemente do raio

Obs: mesma temperatura, mas com ≠s luminosidades

—

90% estrelas estão na sequência principal do diagrama HR.

—

Sequência Principal → são todas as estrelas que queimam Hz no seu núcleo.

—

Cor { Azul → muita massa
Vermelho → baixa massa.

Massa + Hz = posição na sequência principal.

obs: $L \cong M^{3.5}$

1 Sol = 1 L-solar

10 Sol = $10^{3.5}$ Luminosidades solares.

A idade das estrelas

$T = \frac{E\ nucl}{Luminosidade}$ (proporcional à massa)

$T \rightarrow M^{-2.5}$

obs:

10 X massa Solar = 2500 X mais rápido que o Sol

Ex: 30.000.000 (vai perder a luminosidade) na seq. principal.

$\frac{1}{10}$ M Solar = 300 X 10 bilhões de anos = 3 Trilhões Anos.

Usar os cálculos de seu limite para derivar e aprimorar o cálculo do π, como essencial para a obtenção do valor III (MMS).

O limite Chandrasekar tem por base o princípio da exclusão de Pauli, ou seja, dois elétrons não podem ocupar o mesmo espaço ao mesmo tempo. Desta forma, por causa dos estados quânticos, e o mesmo acontece com a anã-branca em que observamos que todos os elementos desta estrela ocupam todos os estados quânticos disponíveis nesta estrela, gerando desta forma, o limite calculado por Chandrasekar. Os elétrons são chamados de degenerados, estando portanto, os elétrons livres em toda a estrela.

Obs.: O mesmo acontece com o cobre, os seus elétrons são degenerados e portanto, alta capacidade de transmissão elétrica e térmica.

20170928

Heliopark
Carapicuíba

20170929

Congresso de Viena 1814-1815
von Metternich (vienense)
↳ até 1848 exerceu a sua influência.

20170929 - 30 (20170930)
Limite Chandrasekar 1930
→ (indiano)
as anãs-brancas não podem ~~passar~~ além de
1.4 massas solares

Quanto maior a massa, menor o raio. (inversão)

Regra geral das estrelas:
Qto maior a massa, maior o raio

Dia 17/10/09

Alimentação:

insulina X glucagon
(acumulador) (queimador)
↳ gordura

Qdo se come muito carboidrato, vou ter muita glicose e quando este está alto, ocorre a diminuição do glucagon.

Glucagon → substância derivada à queima de gordura depositada no corpo.
(uso de reservas energéticas depositadas na forma de gordura.

Evite comer alimentos que aumentem rapidamente o nível de glicose no sangue, pois geram o aumento do nível de insulina no sangue.
Ex.: bolachas (farinha branca)
açúcar

Níveis altos de insulina no sangue impedem a ação do glucagon, ocasionando o depósito de gordura no organismo, impedindo assim, o emagrecimento.

20171010.

Cosmologia trinitária → santíssima trindade

20171012 Cálculo Numérico

integração + polinômio interpolador

↓ de graus maiores (servem para aproximar cada vez mais à real área de medida (integração).

20171017

Equações Aulas 7 e 8.

Grau ímpar sempre tem solução real.

$-\infty$ 0 $+\infty$

↓

mas terá uma raiz real.

Aula 8 - Fatoração. (use sempre)
facilita os cálculos.

equações mais simples.

Cuidado com cancelamento de equações

$$\cancel{x}\, y = \cancel{x}\, z$$

(uma frequente)

$$\frac{\cancel{x} \cdot y}{\cancel{x}} = z$$

(desde q. x seja ≠ zero)

cuidado p/ não dividir por zero.

(cuidado) As vezes pode.

20171010.

Não se pode dividir por zero.

$$3x = 2x$$
$$x = 0$$

obs: Zero multiplicado por qq nº é igual a zero.

$$\frac{x^3 - 5x^2 + 6x}{x-2} = 10$$

Condição:

$x - 2 \neq 0 \iff x \neq 2.$

$$\frac{x(x-2)(x^2-3)}{x-2} = S = \{-2, 5\}$$

agora pode cancelar, porq. $x \neq 0$.

$$x(x-2)(x-3) = 10(x-2)$$

obs: Cancelar pode, só não pode dividir por zero. (veja condição das equações) → de existência

2017/10/10

(3)

$$\sqrt{2x+3} = \sqrt{x-5}$$

$$\left(\sqrt{2x+3}\right)^2 = \left(\sqrt{x-5}\right)^2$$

$$2x+3 = x-5 \Rightarrow x = -8$$

Formalmente é igual, mas

$\sqrt{-13} \Rightarrow$ não é nº real
não é solução.

$$S = \emptyset$$

Temos que testar as raízes.
(sempre).

Obs: $a = b \Rightarrow a^2 = b^2$
$a^2 = b^2 \not\Rightarrow a = b$ } não são equivalentes

Obs: $a^3 = b^3 \Leftrightarrow a = b$.
raízes de índice ímpar não precisa testar as raízes.

20170008 Equações (erros) Portanto: $= x^2 - 5x + 6$ (1)

$$\underbrace{(\cancel{x-2})(x^2-7x+4) = (\cancel{x-2})}_{\text{não pode cancelar.}}(x-3)$$

~~Ver~~ Não se pode dividir por zero.

$0 \cdot x =$ não se pode multiplicar por zero.

$$\frac{(\cancel{x-2})(x^2-7x+4)}{\cancel{x-2}} = x-3$$

não pode, porque está dividindo por zero.

= dividir por zero não

aqui há condição de existência

ex:

$x - 2 \neq 0$

Se houver cond. de existência, pode-se cancelar, mas não dividir por zero.

20171008

(2)

Eq. Irracionais:

$\sqrt{2x+3} = \sqrt{x-5}$

$S = \emptyset$

$x - 8$

$(\sqrt{2x+3})^2 = (\sqrt{x-5})^2$

Temos que testar as raízes.

$2x+3 = x-5$

$x = -8$

$\sqrt{-13} = \sqrt{-13} = S = \emptyset.$

índice par (raiz) = tem que testar

$a^2 = b^2$

ímpar = não precisa testar as raízes.

Jogo:

nº x 3 = y adicione 8

— o nº pensado =

dividir-se por 2 e subtraia o número novamente.

= Resultado 4º

Pag. 18 - 4º diedro

P.H $\equiv \pi_1$ é o Lugar Geométrico (L.G.) → projeção vertical na L.T. } cota do ponto nula (y)

Ex: $E \equiv E_1$ $J \equiv J_1$ ⇒ então na L.T.

Pag. 19 - P.V. $\equiv \pi_2$ ⇒ L.G. afastamento nulo (x) → projeção horizontal na L.T.

G_1, H_1 na L.T.

$G \equiv G_2$ e $H \equiv H_2$

Pag 20 → Pontos pertencentes à L.T.

– projeções coincidem e pertencem à L.T.

Cap. II – Alfabeto da Reta.
posição da reta no plano.

Pag. 22 –

$ABA_\pi B_\pi$ = plano projetante da reta.
⇒ plano projetante vertical.

Pag. 23 – Reta qualquer em Mongeana.

$ABA_2B_2 = \psi$ = projetante de topo da reta.

$ABA_1B_1 = \lambda$ = projetante vertical da reta.

$A_1B_1 = r_1$ e $A_2B_2 = r_2$

é pura

Representa-se pois:

$AB(A_2B_2, A_1B_1)$ ou $AB \equiv (r_2, r_1)$ ou

(A_2B_2, A_1B_1) ou (r_2, r_1)

onde r_2 = projeção vertical e r_1 = projeção horizontal.

20171012 – G.D. Ardevan. (4)

Pág. 24 → Traços de uma reta
pontos de intersecção da reta com os planos de projeção.

Obs.: V = traço vertical H = traço horizontal.
Ângulos = $\hat{\alpha}$, $\hat{\beta}$, $\hat{\theta}$ (letras gregas)

Reta horizontal ou de nível
toda reta paralela ao P.H. $\equiv \pi_1$ (π_1)
→ traço horizontal é um ponto impróprio H_∞.

V.G = Verdadeira Grandeza (Cap. XIV)
um segmento rectilíneo projeta-se em V.G. sobre todo plano que lhe é paralelo, na Projeção Cilíndrica.

Traço Vertical (da reta) → traço da reta em P.V.

$V \equiv V_2$ V_1 = intersecção na L.T.

Épura:

Obs.: A reta horizontal é também chamada de reta de nível.
O ponto V_2 na épura é o seu traço vertical
Todos os seus pontos têm igual cota

20171012 G.D. Andevan (5)

Pág. 25 → Reta Frontal ou de frente.

Toda reta paralela P.V. $\equiv \pi_2$

Seu traço vertical é um ponto impróprio V_∞.

Todos os pontos da reta frontal tem o mesmo afastamento (x)

∴ sua projeção horizontal é paralela L.T.

- Projeção Vertical A_2B_2 do segmento de reta frontal AB dobra-se em V.G.
- O ângulo B que uma reta frontal faz com o P.H. projeta-se em V.G no P.V.
- Seu traço horizontal é o ponto $H \equiv H_1$.

Toda reta paralela P.V é uma reta frontal.

A reta frontal A_1B_1 (AB) tem a projeção A_1B_1 paralela à L.T. e A_2B_2 em V.G.

reta frontal representada pela letra f e suas projeções f_1 e f_2.

A reta frontal f é chamada reta de frente.

Ponto H_1 na épura é o seu traço horizontal

$H \equiv H_1$ e H_2 está L.T.

Pág. 26 → Reta fronto-horizontal ou paralela à L.T. (Fig. 28)

Pág. 27 → Reta de Topo → reta perpendicular ao P.V. $\equiv \pi_2$.

$A_2 \equiv B_2 \equiv V \equiv V_2$

V.G. → A_1, B_1 (Fig. 29)

Pag. 28 → Reta Vertical

reta perpendicular P.H. $\equiv \pi_1$

Traço vertical é o ponto $V_\infty \equiv O_{2\infty}$

V.G. → A_2, B_2, H_2

$H_1 \equiv A_1 \equiv B_1$ (Fig. 31)

AB = reta vertical, que é uma reta frontal vertical.

Reta encontrando a L.T. $A \equiv A_2 \equiv A_1$, B_2, n_2, B_1, n_1

(Fig. 33)

Pág. 29 → Reta de Perfil:

reta contida em um plano α de perfil.

obs.: Plano de Perfil é todo plano perpendicular à L.T.

A reta de perfil é ortogonal ou perpendicular L.T.

A_2, B_2, A_1, B_1 (Fig. 35)

Pág. 30 →

Reta pertencente ao P.H. $\equiv \pi_1$

reta horizontal de cota nula.

projeção vertical sobre L.T.

$A \equiv A_1$ e $B \equiv B_1$

A_2, B_2, $\hat{\alpha}$ em V.G., V.G. (Fig. 37)

Reta pertencente ao P.V. $\equiv \pi_2$

reta frontal de afastamento nulo.

projeção horizontal coincide com L.T.

reta AB pertence ao P.V $\equiv \pi_2$

$A \equiv A_2$ e $B \equiv B_2$

B_2, V.G., A_2, V.G. em B, A_1, B_1 (Fig. 39)

Pág. 31 → Reta pertencente ao 1º bissetor

Todo ponto de uma reta do 1º bissetor tem sua cota igual ao seu afastamento. (Ver. Cap III)

Suas projeções fazem ângulo com L.T.

$B \equiv B_2 \equiv B_1$ (Fig. 41)

Reta pertencente ao 2º bissetor:

Toda reta do 2º bissetor tem as duas projeções coincidentes. (veja Cap. III) (Fig. 42)

Pág. 32 → Reta de maior declive:

Maior ângulo de uma reta de um plano α faz com P.H (III) → chama-se ângulo diedro.

Quando cortado por um plano perpendicular β (fita), obtém-se a reta MN ($M \equiv M_1$) → $M_1 N_1$ é sua projeção horizontal (P.H.).

$\hat{\alpha}$ = ângulo do diedro.

MN pertence ao plano β perpendicular à AB, sendo AB uma reta horizontal.

(Fig. 44)

Veja: (Fig. 241 e 242) Cap. XI → Pág. 135

Reta maior inclinação é a reta do plano α que forma com sua P.V. o maior ângulo possível. (Pag. 33)

Pág. 34 – Cap. III – Alfabeto do plano
representação dos planos dados por seus traços.
Porque um plano pode ocupar em relação aos planos de projeção.
Traços de um plano → intersecções com os planos de projeção π_1 e π_2.
t Traço vertical no espaço, de um plano, será t + índice que individualiza o plano.
Plano α = t_α (Fig. 45)
A projeção vertical deste traço vertical t_α é a reta $t_{\alpha 2}$, coincidente com t_α.
s Traço horizontal = s + índice do plano
plano α terá traço horizontal = s_α.
A projeção horizontal de s_α = é a reta $s_{\alpha 1}$, coincidente com s_α (Fig. 46).
A projeção horizontal $t_{\alpha 1}$ do traço $t_{\alpha 2}$ irá coincidir com a L.T. (Fig. 45).

Pág. 35 → Plano qualquer α: $t_\alpha \equiv t_{\alpha 2}$
$s_\alpha \equiv s_{\alpha 1}$.

$t_\alpha \equiv t_{\alpha 2}$ ⇒ traço vertical do plano α.
sua projeção coincide com L.T.
$s_\alpha \equiv s_{\alpha 1}$ ⇒ traço horizontal do plano α.
sua projeção vertical $s_{\alpha 2}$ coincide com L.T.

A2 pertence $t_{\alpha 2}$.
A1 pertence $t_{\alpha 1}$.

Pág. 36 → Traços de um plano qualquer α.

(Fig. 48)
Pág. 37

Obs.: $s_{\alpha 1A}$ → é o traço horizontal do plano α com π_1 A.
$s_{\alpha 1P}$ → traço horizontal do plano α com π_1 P.

são uma só reta, que é a intersecção do plano α com o plano π_1.

Pág. 38 → Plano horizontal:
Todo plano paralelo ao plano horizontal (P.H.) de projeção. → ω
ω // π_1 ⇒ tem traço vertical próprio, paralelo à L.T. designado t_ω no espaço e por $t_{\omega 2}$ na épura, sendo o seu traço horizontal uma reta imprópria.

→ projeção horizontal
Important. O plano ω horizontal é também (chamado) de nominado plano de nível e é o L.G. dos pontos de uma mesma cota.

Pag. 38 → Plano frontal:

(Fig. 50)

Pág. 38 → Plano Frontal:

Todo plano paralelo ao plano vertical de projeção. Designado por φ. $\varphi // P.V.$

Tem apenas traço horizontal (s) próprio, designado pela letra s_φ.

Este traço é paralelo L.T.

∴ s_φ → na epura $s_{\varphi 1}$

(Fig. 52)

Pág. 39 → Plano de Topo:

Todo plano perpendicular ao P.V. projetante.

Designado ⇒ ψ

Todas as retas projetantes são retas de topo.

O plano ψ de topo é um plano projetante.

obs.: Traço horizontal $s_{\psi 1}$ do plano ψ de topo é perpendicular L.T.

(representa-se apenas pelo seu traço vertical.

(Fig. 55)

(Fig. 54)

obs.: Toda figura pertencente a um plano ψ de topo tem seu P.V. sobre o traço vertical $t_{\psi 2}$ do mesmo.

obs.: O ângulo α que um plano ψ de topo forma com o P.H. projeta-se em V.G no P.V.

Pág. 40 → Plano de Topo (cont.)

Plano vertical → Todo plano perpendicular ao plano horizontal (P.H.) de projeção, designado ⇒ λ.

Todas as retas projetantes, contidas em um plano vertical, são retas verticais.

Plano vertical é um plano projetante.

(Fig. 57)

(Fig. 58)

Pág. 41 → Plano de Perfil: (20171015)

(Fig. 60)

Todo plano α perpendicular L.T. ⇒ perpendicular P.H e P.V.

plano de perfil.

Toda figura pertencente a um plano α de perfil tem suas projeções sobre os traços do mesmo.

Pág. 42 → Plano paralelo à L.T. ou de ângulos complementares.

Plano α paralelo à L.T.

Traços verticais t_α e horizontal s_α são paralelos à L.T.

(Fig. 62)

20171015 G.D. Andevan

Pág. 43 → $\hat{\alpha} + \hat{\beta} + 90° = 180°$, logo
$\hat{\alpha} + \hat{\beta} = 90°$

Este plano é também denominado de plano de rampa.

Planos bissetores: plano bissetor de um diedro é o plano β que o divide em 2 diedros iguais. Os 2 planos de projeção (β_i e β_p) são perpendiculares entre si, teremos:

a) Plano bissetor do 1.º e 3.º diedros ⇒ β_i chama-se plano de simetria ou bissetor ímpar

b) Plano bissetor do 2.º e 4.º diedros ⇒ β_p chama-se plano de coincidência ou bissetor par. (Fig. 63)

∴ Todo ponto contido no 1.º ou no 2.º bissetor tem cota e afastamento iguais, ou seja, dista igualmente do P.H. e do P.V.

(Fig. 64)

(Fig. 65)

$A_2 A_0 = A_0 A_1$

Pág. 44 → Plano qualquer perpendicular ao 1.º bissetor

Pág. 45 → Logo, na figura, todo plano α cujos traços vertical e horizontal façam o mesmo ângulo θ com a L.T. é perpendicular ao 1º bissetor Bi.

Plano qualquer perpendicular ao 2º bissetor:

(Fig. 69)

Pág. 46 → Plano perpendicular ao 2º bissetor, considerados os prolongamentos de seus traços.

(Fig. 71)

Veja: Fig. 48

Obs: Todo plano que contenha uma reta perpendicular ao 1º bissetor é perpendicular ao mesmo. O mesmo ocorre com o 2º bissetor.

Retas perpendiculares ao 1º ou ao 2º bissetor são retas de perfil.

Planos perpendiculares aos bissetores fazem ângulos iguais no espaço ao P.H. ≡ π_1 e com o P.V. ≡ π_2.

Pág. 47 → Plano Mediador de AB:

É o plano α que contém o ponto M médio do segmento AB e é perpendicular à AB.

É o lugar geométrico (L.G.) dos pontos que equidistam dos pontos A e B.

Um ponto de uma reta r que equidista de dois pontos dados A e B será pois o ponto F onde a reta r fura o plano mediador α do segmento AB.

20171015 G.D. Ardevan

Pág. 48 → Cap. IV

Determinação dos traços de retas quaisquer com os planos de projeção. Traços de uma reta de perfil.

Traços de uma reta: (20171018)

Traços de uma reta são os pontos de intersecção da mesma com os planos de projeção π_1 e π_2.

intersecção com: { P.H. → traço H.
P.V. → traço V.

(Fig. 73).

(Fig. 74)

Pág. 50 → Determinação dos traços de uma reta de perfil

→ Rebatimento (coloque um r depois de cada letra que foi rebatida sobre o plano de projeção)

→ arcos de circunferência em torno de t_α (traço vertical).

obs.: Os centros estão sobre o eixo rotacionado (que foi rebatido no plano de projeção)

Ex.: Neste caso, em projeção vertical descreverão retas paralelas à L.T.

Pág. 52 → Problema.

Pág. 53 → Ponto pertencente a uma reta de perfil AB.

2017 10 15

Usar trigonometria para interligar os pontos gerados de cada circunferência

Com 3 circunferências

Com 4 circunferências

usar T. de Pitágoras com log trigonométricos.

Usar as discrepâncias numéricas entre os valores obtidos de cometer das predições das distâncias entre os pontos cuja origem são de cada circunferência (pontos), ou seja, um ponto de uma circunferência e o ponto de outra, usar os log e comparar com a tabela de log. trigonométricos.

obs: □4526 + □5663 + $\frac{11}{7}$ = ⊙ B

esta área está no círculo superior

(5) Descrever as equações dos seguintes arcos: $\widehat{AB}$, $\widehat{AC}$ e $\widehat{BC}$ como as equações, calcular a área. (integral)

(6) Calcular o volume do triângulo retângulo e retângulo do triângulo de base ABC

I < II

Calcular as áreas (propriedades).

Juntar os triângulos na parte superior num único ponto. Portanto, juntar os pontos DEF em um único ponto e calcular o volume: triângulos com linhas retas e curvas.

(7) Perante o arco: meça o comprimento da corda $\overline{AC}$ e compare com o comprimento da corda $\overline{AC}$, caso ele esteja no mesmo segmento de corda, calcule a função desta corda.

Repita o mesmo cálculo com as simulações com 4 círculos.

II < I

Veja as proporções entre eles e suas respectivas áreas.

$\Delta II \times x = \Delta I$ $\quad$ $\square II \times x = \square I$

$\Delta II \times y = \square II$ $\quad$ ~~$\square II \times y = \square II$~~

$\Delta II \times y = \square II$

Faça os cálculos usando:

$\Delta I \times y < \square II$

$\Delta II \times y = \square I$

$\Delta I \times a = \square II$ e $\square I$

(8) Finalmente, calcule os logaritmos entre os arcos nas simulações com 3 arcos e 4 arcos. Veja distâncias entre os arcos em 2 dimensões e 3 dimensões. 20171209 0040

100 | 0,35

(Bom) estudos!!

Calculo a regra

7 p/ 10

7 p/ 20

1 ÷ 7 =

1 | 7

0,142857

vejamos: Calcule também

(1) 20 ÷ 7 = 2,857142 ÷ 0,142857 = x

observe que mudou a ordem dos números depois da vírgula, 857142 142857 (joker; porquê?)

(2) 7 ÷ 20 = 0,35 ÷ 0,142857 = y

(3) 7 ÷ 10 = 0,7 ÷ 0,142857 = z

0,142857 (comparar com √2)

Calcule também

A + B = 39 + 39 = 78

20 × 20 = 400
78
322

veja √322

2017120901 3.8 . . . . . 1 1

Área ②

$$\begin{array}{r} 19 \\ \times\ 19 \\ \hline 171 \\ 19 \\ \hline 361 \end{array} \qquad \begin{array}{r} 20 \\ \times\ 20 \\ \hline \end{array}$$

361 400 = 39 veja $\sqrt{39}$

↳ veja log.

$6 \times 6 = 36$ ↳ faltam 3

$7 \times 7 = 49$

$49 - 36 = 13$ (ímpar e primo)

A raiz de 36 está entre:

$6{,}2 < \sqrt{39} < 6{,}3$ (outro jeito)

vai ajudar

$$\begin{array}{r} 6{,}2 \\ \times\ 6{,}2 \\ \hline 124 \\ 372 \\ \hline 38{,}44 \end{array} \qquad \begin{array}{r} 6{,}3 \\ \times\ 6{,}3 \\ \hline 189 \\ 378 \\ \hline 39{,}69 \end{array} \qquad \begin{array}{r} 39{,}69 \\ -\ 38{,}44 \\ \hline 1{,}25 \end{array}$$

interessante!!! (estudar)

~~de onde veio isso~~

$0{,}25 = \frac{1}{4}$ estudar na simulação de 4 círculos

00
00

está certo!!!

Veja: $\sqrt{1,25}$.

Veja log 1,25

Veja também: $6 \div 1,25 = 4,8$

$1,25 \div 6 = 0,2083\overline{3}$

20171209 0155.

2017/2/13.09.30 ..... / /

$$\cong A \times 3+\frac{1}{7} = B$$

14π

vejamos:

$$A \times 3+\frac{1}{7} = B \Rightarrow 7\left(A \times 3+\frac{1}{7}\right) = 7B$$

$$\Rightarrow 7A \times 21 + 7\frac{1}{7} \Rightarrow$$

$$\Rightarrow 7A \times 22 = 7B \quad (7 \times 2\pi)$$

$14(\pi)$.

valor

fazer simulação com 7 circunferências

(volume)

obs: $3{,}5\pi \times 22 = 7B\ (14\pi) \Rightarrow$ $(43{,}98229\ldots)$ (y)

$77\pi =$ $(241{,}902634\ldots)$ (x)

$x \div y = 5{,}5\ (?)$

Esta diferença deve-se ao erro de área do quadrado A em relação à circunferência B

$$A = \frac{\pi}{2} \Rightarrow 7A = 7\frac{\pi}{2} = 3+\frac{1}{2}\pi \Rightarrow 7A = 3{,}5\pi$$

$3{,}5\pi$

obs.: vejamos outro aspecto:

$X\ 22 = 7B\ (14\ II)$

$\hookrightarrow 22 \div 2 = 11$

$\hookrightarrow \div 2 = 5,5$

ver a relação 5,5 (direita) com o outro 5,5?

Axioms → the truths of wich are self-evident.
They are incapable of demonstration

Propositions → which are not axioms are properties of figures obtained by processes of reasoning.
- Theorems.
- Problems.

Theorem → is the formal statement of a property that may be demonstrated from known proposition.
These propositions may themselves be theorems or axioms.
A theorem consists of two parts, the hypothesis, or that which is assumed, and the conclusion, or that which is asserted to follow therefrom.
- hypothesis.
- conclusion.

obs: converse theorems.

obs: From the two theorems, we may infer two others, called their contrapositives. (obverse)
the contrapositives are obverse from first theorem.

Problem is a proposition in which something is proposed to be done or a figure to be constructed,

under some given conditions.

Solution – method of construction

Demonstration is the proof.
In the case of a theorem, that the conclusion follows from the hypothesis;
and in the case of a problem, that the construction accomplishes the object proposed.

Enunciation → of a problem
two parts → data or things supposed to be given
→ quaesita or things required to be done.

Postulates → are the elements of geometrical construction, and occupy the same relation with respect to problems as axioms do to theorem.

A Corollary is an inference or deduction from a proposition.

A Lemma is an auxiliary proposition required in the demonstration of a principal proposition.

Carl Wilhelm Ferdinand

↓ Duque de Braunschweig

patrimonio

Carl Friedrich Gauss

His breakthrough occurred in 1796 when he showed that a regular polygon can be constructed by compass and straightedge if the number of its sides is the product of distinct Fermat primes and power of 2.(12)

20180416.

Projeção $1=\sqrt{2}$ (já sabia)

C e D e E

$-\sqrt{2}$ e $\sqrt{2}$ e $\sqrt{2}$

20180416

(circle through 3 points)

circle A E B. (3 pontos)

②

Perpendicular Bisector $\overline{AB}$

Para calcular a reta que passa pelo ponto G (mediatriz) use a regra do triângulo retângulo.

Perpendicular Bisector $\overline{EF}$

20180421. Circle Mediatrices

2.1

Construção: $\sqrt{2}$

1) Point A(0,0) Point B(1,0)
Point C(1,1)

2) Trace a linha entre os pontos A e C (45°)

3) Faça o círculo $\hat{AB}$ (Circle through B with center A)

4) Marque a intersecção deste círculo com a linha AB.
Obteremos um Point Intersect (0.7071067811865475, 0.7071...)

5) ~~Faça o segmento (Segment)~~
Crie os pontos E(2,0) e F(0,2)

6) Faça o segmento (Segment)
F(0,2) com o point D(0,707..., 0,707...)

7) Faça uma linha perpendicular ~~ao~~ no ponto F com base no segmento FD, criando um ângulo de 90°.
(Line through FD perpendicular to g).

8) A intersecção desta reta perpendicular

com a linha $\overline{AC}$ marcamos um ponto de interseção (G)
→ Intersect (f, h)
(4.4142..., 4.4142...) (1ª solução)

9) Divida o segmento $\overline{DG}$ (Bisector) (dá para fazer com um compasso).
(Perpendicular Bisector $\overline{DG}$)
marcamos o ponto de interseção H
(f, i) (2.5606601717798 21, 2.56066...)

10) Circle with Center through Point (2, 0). Obs.: Se preferência uma os 3 pontos F, D, E com a circunferência e centro H.

11) Crie 2 novos pontos de interseção, onde este círculo intercepta os eixos x e y.
eixo x → Point I (3.1213203435596410)
eixo y → Point J (0, 3.1213203435596410)

12) Faça o segmento $\overline{JI}$ (4.4142135623 7...), (2ª solução) o ponto de interseção deste segmento com a linha $\overline{AC}$, obteremos o ponto de interseção K (1.5606601717798 21, 1.56...)

13) Crie o segmento $\overline{KH}$ (Segment (K, H)) → obteremos
1.4142135623730 96...
($\sqrt{2}$) (3ª solução)

20190421 Circle Mediating
(20180421)

2-2

14) Crie os pontos L(3,1), T(3,6) e faça o segmento $\overline{LT}$ (tamanho 5);

15) Crie PerpendicularLine(G, l) (Point, Line), com a intersecção desta perpendicular com a reta l, teremos a intersecção U (Intersect(m, l) ≡ (3, 4.414213562373094)

16) Faça um novo segmento $\overline{UG}$ = 1.414213562373094... (4ª solução)

Obs. Item 7 – perpendicular no ponto (Point) F.

Esta construção geométrica, serve para achar o centro de um círculo.

21.9 Um pouco de história.

1º a calcular a área exata de uma figura limitada por curvas foi:

Hipócrates de Chios
(Sec. V A.C.)

Ele calculou a área da figura em forma de lua crescente (ou minguante).

Lúnulas de Hipócrates.

→ a sua área é igual à área do quadrado cujo lado é o raio do círculo.

20180417 Pitagoras (Nano)

faço o deslocamento de uma unidade à esquerda

ver qual a função que tem este resultado.

Obs:

Outra equação $3\sqrt{2}$

(ver qual função! seno, cos, tag etc.

Importante:

Calcular a circunferência: área, circunferência

na hipótese do ponto coincidir com raio

$\rightarrow 3{,}12$

(simular)

20180421 $\sqrt{2}$ (cont.)

(2)

Simular $\sqrt{2}$ como sendo 1,4142, caso os pontos de intersecção sobre o eixo x e eixo y sejam 3,12. Veja se há correlação direta.

Hipótese

(Teorema)

Tente fazer a prova da $\sqrt{2}$ na qual a $\sqrt{2}$ corresponde a um quadrado circunscrito de um círculo cujo raio seja igual a 1.

- Faça os cálculos de área e distância entre os pontos manualmente, não confie nas demonstrações obtidas dos programas gráficos, não se esquecendo do problema da quadratura do círculo.

  ↳ fazer checagem mais detalhada.

Evite usar o círculo nas demonstrações, use mais as retas e intersecções, o círculo serve mais de parâmetro para ajustes dos ruins a serem seguidos no uso das retas.

Caso faça a hipótese de utilizarmos os pontos sobre os

20180421 — T2 (cont.)

eixos x (3, 12, 0) e
eixo y (0, 3, 12),

se se confirmarem que estes valores atendem aos critérios preestabelecidos, neste caso, utilizaremos o círculo como mais uma fonte de prova dos valores obtidos.

Baldor (Nueva Edición)

20180423 T2 Nova Construção

(1)

1) A(0,0) B(1,0) C(1,1) D(3,0) E(0,3)

2) Faça uma linha $\overline{AB}$ $(-x+y \neq 0)$ (igual) $\Rightarrow (-x+y=0)$

3) Faça um segmento $\overline{DE}$

4) A intersecção da linha $\overline{AB}$ com o segmento $\overline{DE}$, criaremos o ponto F(1.5, 1.5)

Obs: A distância $\overline{DF} = 2.121320343559642$
Com este segmento colocaremos o compasso sobre o ponto B(1,0) e estabeleceremos sobre o eixo x.
Faça o mesmo sobre o eixo y.
(Ponto 0,1)

5) Crie o point G(0,1) para o eixo y)

6) Faça uma Perpendicular Line (E, g)
$(-x+y=3)$
Obs: Será usado para achar o centro do círculo (que intercepta a linha $\overline{AC}$).

7) Crie o segmento $\overline{DF}$ (i) i: Segment(D,F)

~~8) Usa o comando DUPLICATE será criado um novo segmento, edite-o desta forma:~~

~~x = Segment(D,F)(1,5, 0).~~
~~→ será sobre o eixo x~~
(eixo)

20180423 $\sqrt{2}$ Nova Construção

(2)

8 cont: off: Segment $\left(\frac{D}{2}, \frac{F}{2}\right)$ (2,0) = (2.1213...
0)
(não dá neste caso)

8) Use um compasso:
A) Pegue a distância $\overline{DF}$ e coloque sobre o ponto B(1, 0) e intercepte o eixo x;
B) Faça o mesmo no ponto G(0,1) e intercepte o eixo y.

9) Faça o segmento $\overline{HI}$ (4.4142135....)
$3+\sqrt{2}$

10) Faça o segmento B(1,0) E(0,3) e faça uma perpendicular Line sobre (0,3).

Perpendicular Line(E, R)
↳ segment.

' A intersecção desta perpendicular com a linha $\overline{AC}$, criaremos o point J(4.5, 4.5).

11) Important:

A linha $\overline{BE}$ que intersecciona com a linha $\overline{AC}$ no point (0.75, 0.75)

(erro) vamos analisar!!!

20180423 $\sqrt{2}$ Nova Construção

(3)

Antes de continuarmos! (1º Quadrante)

Segment (H, I) (1, 0) → o vector ficará sobre o eixo X.

Segment (H, I) (1 1) → fica no eixo bisector entre o eixo x e eixo y.
(1, 1)

Segment (H, I) (0, 1) → fica sobre o eixo y.

Obs.:

Segment (H, I) (1, 1) - 3 (1.4142..., 1.4142...)

(dá para colocar em qualquer direção e sentido).

Obs:

bisector entre x e y.

Segment (H, I) - 0 (1, 0) - 3 ⇒ (1.4142... 1.4142...)

-1
-2 tamanho seta.
-3 → para cima no 1º quadrante.

Aprimoramento:

Segment (J, Segment (H, I) - 3)

Segment (J, Segment (H, I) - 3) (2, 2)
⇒ Point (2.8284... 2.8284...)

20180423 T2 Nova Construção

No programa aparece:

Segment(J, Point(Circle(J, Segment(H,I) - 3)))(2,2)

Important

Para criar a inclinação da reta de tamanho $\sqrt{2}$ sobre a linha $\overline{AC}$

K = Point(Circle(J, Segment(H,I)-3))

ATENTION:

Use o comando:

Segment(H,I)(1,1)-3

1 vez

Segment(J, Segment(H,I)-3)

Clique no point K e arraste até a linha $\overline{AC}$.

O Ponto K é o centro da circunferência.

Source: square_root_of_2_use

da_matriz_calculo_centro_circulo_triângulo_retângulo_20180421_016_6a_versão_teste_10.ggb

Obs: não precisou o uso do triângulo retângulo.

Mas se usar, você verá que o ponto K coincidirá com a intersecção da reta FN com a linha AC.

Atenção:

$\overline{DF} = 2.121320343559643$

$\overline{LF} = 1.121320343559642$

$\overline{LF} + 1 = \overline{DF}$

Hamiltonian for the zeros of the Riemann zeta function.

Bender, Brody, Müller.

obs.:

Atiyah has spoken about connections between mathematics and physics for years.

he claims yields RH as a corollary!

Maybe he was alluding to his work on the the fine structure constant which he claims yields as a corollary.

Fine Structure Constant

is a dimensionless physical constant α, given by

$$\alpha = \frac{e^2}{4\pi\varepsilon_0 \hbar c}$$

where:

e is the element charge

$\hbar$ is the reduced Planck constant and

c is the speed of light in vacuum.

Its value is roughly (±)

1/137

obs:

O Kg é utilizado para definir outras 3 unidades básicas do Sistema Internacional

- candela
- ampere
- mol

e 17 unidades derivadas, tais como o joule e o newton.

Metro ⇒ 1983

$1/299.792.458$ m/s

Kg → precisa ser definido um valor numérico de uma constante natural.

Químicos → escolheram o Avogadro

Físicos → constante de Planck (que relaciona a energia de um fóton com a frequência de seu onda).

<u>obs</u>: A constante de Avogadro que foi definida medindo a quantidade de átomos em uma esfera perfeita de silício, também será usada para redefinir o mol.

Ampére → balança de Watt, um instrumento que equaciona a potência eletromagnética (que depende de uma corrente) com a potência mecânica (que depende de uma força, o peso).

Primeiro, uma corrente conhecida é aplicada. Calculado o peso correspondente na balança, é possível obter a massa exata, sendo quilo, uma vez que a aceleração da gravidade é conhecida.

"Percebemos que um experimento poderia medir a constante de Planck", lembra Phillips (NIST)

William Phillips
Nobel Física 1997.

A partir daí, redefinir o quilo era um passo lógico, já que a constante de Planck é medida em uma combinação de unidades que inclui a de massa.

Definiram o valor da constante de Planck [e do número de ~~Avogo~~ progredo].

Os metrologos desenvolveram métodos para fixar a constante de Boltzmann, que definirá o Kelvin, e a constante de carga elementar.

As outras unidades físicas o segundo, metro e candela já estão definidas por constantes físicas.

h

Kg → "constante de Planck"

uso do Balanço de Kibble, que faz uso da constante para medir a massa de um objeto usando uma força eletromagnética medida com precisão.

Max Planck (1900)
produto de uma energia por um tempo.

E a energia está ligada à massa pela célebre equação $E = mc^2$

$h = 6,62607015 \times 10^{-34}$ J/s.

Balança do watt, também chamada balança de Kibble, por conta do seu inventor, o físico britânico Bryan Kibble, e que consiste em converter uma massa em potência elétrica.

20181117

Esfericidade do elétron

momento dipolar de partícula-onda.

Embora seja impraticável hoje medir um momento dipolar igual a zero e afirmar que o elétron é absolutamente esférico, a equipe concluiu que o momento dipolar não é maior do que zero com uma precisão muito grande.

O elétron parece ser esférico até uma magnitude de

0,000 000 000 000 000 000 000 000 000 1 cm

mais precisamente $8,7 \times 10^{-29}$ cm.

Isso não abala em nada o Modelo Padrão que aguenta uma esfericidade de até

10^{-39} cm

http://arxiv.org/abs/1310.7534.

Abstract Differential Geometry (ADG).

↓

based on sheaf theoretic methods, without use of ordinary calculus.

theory of sheaves

Sheaf

Especially in algebraic geometry and the theory of complex manifolds, sheaf cohomology provides a powerful link between topological and geometric properties of spaces.

Sheaves also provide the basis for the theory of D-modules, which provide applications to the theory of differential equations.

João 8, 41:

"Nós não nascemos da prostituição! Temos um só pai, Deus!"

Comentário:

Os Judeus falaram isso de Jesus Cristo, pois sua mãe Maria havia engravidado enquanto José ainda era noivo dela.

Para os judeus isso era um pecado pois havia sido cometido um adultério e fora das leis de Israel e portanto, decorrente da prostituição.

Eles falaram isso para ofender Jesus: "Nós não nascemos da prostituição!" e em seguida: "Temos um só pai, Deus!", afirmando que eles foram concebidos de acordo com as leis judaicas.

—

João 8, 47:

"Aquele que é de Deus escuta as palavras de Deus; e é porque não sois de Deus que vós não me escutais!"

MATÉRIA 20190104 DATA

$$\pi = \frac{C}{2r} \qquad A = \pi \cdot r^2$$

$$A = \pi r^2 \qquad C = 2\pi r$$

$$A = \pi \left(\frac{d}{2}\right)^2 \qquad D = \frac{C}{\pi}$$

$$A = \pi \left(\frac{d^2}{4}\right) \Rightarrow \pi = \frac{A}{\left(\frac{d^2}{4}\right)}$$

$$\Downarrow$$

$$\pi = A \times \frac{4}{d^2}$$

$$\cancel{\pi = 4 A d^2}$$

$$\pi = A \times \frac{4}{d^2}$$

$$\frac{A d^2 \times 4}{d^2} = \cancel{\frac{A A d^2}{d^2}} \quad \frac{4 A d^2}{d^2}$$

$$A = \pi \left(\frac{d}{2}\right)^2 \Rightarrow \pi = \cancel{\frac{1}{\frac{2}{4}}}$$

$$\left(\frac{1}{4}\right)^2 = \cancel{\frac{1}{\frac{1}{4}}} \qquad \frac{1}{4} \times \frac{1}{4} = \frac{1}{16} = 0{,}625$$

$0{,}625$

$$\frac{1}{4} = \sqrt{\frac{1}{16}}$$

$$\frac{1}{\frac{1}{4}} = 4$$

$$\boxed{\left(\frac{1}{4}\right)^2 = \cancel{\frac{1}{\left(\frac{1}{4}\right)^2}} \quad \frac{1}{4^2}}$$

$$A = \pi \left(\frac{d}{2}\right)^2 = \pi \frac{1}{\left(\frac{2}{d}\right)^2} = \frac{\pi}{\left(\frac{2}{d}\right)^2}$$

$$A = \frac{\pi}{\frac{4}{d^2}} = \frac{\pi}{\frac{4}{d^2}}$$

20190104

$\pi = 3{,}14\ldots$

Se você deformar o espaço usando equações quânticas até obter-se o $\pi = 3$ ou outro valor exato mais próximo.

3,11
3,12
3,13
3,14
3,15

Usar cálculos
$\sqrt{2} + \sqrt{3}$
$\sqrt{2}\ \sqrt{3}$

$$\frac{\sqrt{2}\ \sqrt{3}}{\frac{\sqrt{2}}{\sqrt{3}}} = 3$$

$$\frac{\sqrt{2}\ \sqrt{3}}{\frac{\sqrt{3}}{\sqrt{2}}} = 2$$

Usando isto com a deformação do espaço, veja também relações trigonométricas, poderemos obter uma nova equação para o cálculo do π.

deformação espacial
obs: uso cálculo vetoriais.

Você efetuando isso você terá uma circunferência menor e poderá obter um número mais preciso do π com um coeficiente vetorial espacial quântico sporte à deformação do espaço tridimensional.

Produção de energia elétrica por meio do efeito fotovoltaico

Função de onda. (emaranhamento quântico).

Efeito Fotoelétrico → Heinrich Hertz

A emissão de elétrons de uma superfície em razão da interação de uma onda eletromagnética com a mesma é chamada efeito fotoelétrico.

A velocidade com que os elétrons são ejetados não depende da quantidade de fótons emitidos, e sim da frequência que estes fótons possuem;

$E_f = E_c + W$

W → Função Trabalho (J)

E_c → Energia Cinética (J)

E_f → Energia do fóton (J)

$$h.f = \frac{mv^2}{2} + W$$

1921 - Einstein recebeu o Prêmio Nobel

(por causa deste efeito).

$$e^{\pi i/2} = i$$

$$e^{\pi} = i^{-2i}$$

obs.: Given that $e^{\pi i/2} = i$ if we take the principal branch of the logarithm, then we see that $\frac{\pi i}{2} = \log i$

Some basic algebra reveals that

$\pi = 2i \log i$, which implies that

$$e^{\pi} = e^{-2i \log i}.$$

Hence we are led to the identity

$$e^{\pi} = i^{-2i},$$

and discover that the number that was center stage of this entire chapter can

be expressed as an algebraic number raised to an algebraic exponent.

Geometric ... 2009.pdf

Pág. 19 (30)

Fig. 1.1

The magnitude of a blade $a \wedge b$ is the area of the parallelogram spanned by a and b

$$ab = a * b + a \wedge b.$$

That is, the geometric product of two vectors results in the sum of a scalar and a grade 2 vector (also called a bivector).

... certain subalgebras of geometric algebra are isomorphic to complex numbers.

This can be seen quite easily by first evaluating the square of the bivector $e_1 e_2 \in G_3$:

$$(e_{12})^2 = e_{12} e_{12} = -(e_1 e_2)(e_2 e_1) =$$
$$-e_1(e_2 e_2) e_1 = -(e_1 e_1) = -1$$

This shows that bivectors in geometric algebra square to minus 1.

Using the simple rules of the geometric product for orthonormal basis vectors, ... entities of the type

$w = a + b e_{12}$ behave in the same way as complex numbers

$w = a + ib$, where $i := \sqrt{-1}$ denotes the imaginary unit (see Sect. 3.8.2)

T. Geral da Relatividade

Desvio causado pelo Sol:

1,75 arcossegundo.

Obs.: dobro do que sugeria a velha teoria de Isaac Newton.

Eclipse Solar 29 Maio 1919.

A duração seria a maior desde 1416, o que estimulou a Sociedade Real do Reino Unido a promover 2 expedições,

uma para Sobral, no Ceará, e outra para a Ilha do Príncipe, África.

A alteração é o mesmo que estar sob a influência de um campo gravitacional. Se variações de velocidade alteram a geometria do espaço-tempo, objetos que geram gravidade também devem fazê-lo.

O que se curva são as próprias leis da geometria.

A luz é exatamente o que esquadrinha essa geometria.

Quando ela faz uma curva, na verdade está andando em linha reta, mas num espaço curvo.

Einstein usou o trabalho do matemático Georg Riemann para fazer o seu embasamento matemático.

1,75" seg de arco, uma medida equivalente a modesto 0,00048 grau.

Duração do eclipse em Sobral → 6 minutos e 51 segundos.

Henrique Morize, diretor do Observatório Nacional, RJ, enviou alerta para várias organizações no mundo, inclusive a Sociedade Real Astronômica, liderados por Eddington e Dyson.

20190527 Einstein

Sobral → comandada por Charles Davidson e Andrew Crommelin

Príncipe → Eddington.

Einstein veio ao Brasil em 1925 e disse:

"O problema que minha mente formulou foi respondido pelo luminoso céu do Brasil."

20190529 π (1)

$\pi = \frac{C}{D}$ ou $2r$ perímetro de uma circunferência e seu diâmetro.

Em aplicações com mais de duas ~~aplicações~~, (dimensões) como duas vezes o menor valor positivo de x quando $\cos(x)=0$.

É um número irracional, mas, ao mesmo tempo, ele também não é um número algébrico (ou seja, não pode ser a raiz de uma equação polinomial diferente de zero com coeficientes racionais).

14 março
- 1879 → nascimento de Albert Einstein
- 2018 → morte de Stephen Hawking.

π – papiro de Ahmes $\left(\frac{4}{3}\right)^4$, embora também seja encontrado o valor $3\frac{1}{6}$.

Babilônios → $3\frac{1}{8}$

Arquimedes → $\frac{223}{71} < \pi < \frac{22}{7}$

Veja:

matemático hindu Aryabhata

$$(4+100).8+62000 \cong \pi . 20.000$$
(diâmetro)

$$104.8+62000 \cong \pi . 20000$$
$$832+62000 \cong \pi . 20000$$
$$\frac{62832}{20.000} \cong \pi$$

$\pi \Rightarrow$ aproximação que representa diferença de aproximadamente $2,7 \times 10^{-7}$ =

$$\frac{355}{113} \cong \pi$$

Arquimedes $\Rightarrow$

Polígono de n lados e raio 1, temos a medida do lado expressa pela lei dos cossenos:

$$a^2 = b^2 + c^2 - 2bc \cos \alpha$$

Temos formado um triângulo isósceles, de base l e lados $r = 1$: (α)

$$l^2 = r^2 + r^2 - 2r^2 \cos \alpha$$
$$l^2 = 1^2 + 1^2 - 2 \cos \alpha$$
$$l^2 = 2 - 2 \cos \alpha$$
$$l = \sqrt{2 - 2 \cos \alpha}$$

O ângulo do triângulo isósceles no centro do polígono é expresso por 360° dividido pelo número de lados $\underline{n}$, portanto:

20190529 π

(2)

$$C = \sqrt{2 - 2\cos\left(\frac{360}{n}\right)}$$

Dessa forma, (acabou a careta) o perímetro do polígono será de:

$$P = n \cdot \sqrt{2 - 2\cos\left(\frac{360}{n}\right)}$$

Como o π é representado pelo perímetro do polígono dividido pelo seu diâmetro, teremos:

$$\pi = n \cdot \sqrt{\frac{2 - 2\cos\left(\frac{360}{n}\right)}{2}}$$

Aplicando as transformações trigonométricas, a fórmula acima pode ser simplificada para:

$$\pi = n \cdot \operatorname{sen}\left(\frac{180}{n}\right)$$

A Grande Pirâmide de Gizé parece aproximar-se do pi. A altura vertical da pirâmide tem a mesma relação com o perímetro de sua base como o raio de um círculo tem a sua circunferência.

Filme de Darren Aronofsky π

(Pi: Faith in Chaos)

Os primeiros 144 dígitos de pi somam 666
(marca da besta)

$$144 = (6+6) \times (6+6)$$

20190529/ Geometric Methods and Applications for Computer and Engineering/ Geometric ... (2011).pdf
Pág. 192 (221)
Fig. 6.2 - The Gram-Schmidt orthonormalization procedure.

Obs: Ref. Lemma 6.7. (Pág. 191)

Given any nontrivial Euclidean space E of finite dimension $n \geq 1$, from any basis $(e_1, \dots, e_n)$ for E we can construct an orthonormal basis $(u_1, \dots, u_n)$ for E, with the property that for every k, $1 \leq k \leq n$, the families $(e_1, \dots, e_k)$ and $(u_1, \dots, u_k)$ generate the same subspace.

Orthonormality – in linear algebra, two vectors in an inner product space are orthonormal if they are orthogonal and unit vectors.

obs: ~~An~~ (A set of vectors form an orthonormal set if all vectors in the set are mutually orthogonal and all of unit length.

An orthonormal set which forms a basis is called an orthonormal basis.

inner product space → a scalar function of two vectors, equal to the product of their magnitudes and the cosine of the angle between them.

obs: An inner product of two vectors represents the number of changes along the shared branch vectors.

obs: Orthogonality between vectors (zero inner product).

Inner product spaces generalize Euclidean spaces (in which the inner product is the dot product, also know as the scalar product) to vector spaces of any (possibly infinite) dimension, and are studied in functional analysis.

obs: Geometric interpretation of the angle between two vectors defined using as inner product.

$\theta = \arccos(x \cdot y / |x||y|)$

MATÉRIA 20190610. DATA

homeomorfismo → "geometria flexível"!

⇒ Duas formas são a mesma se for possível transformar uma em outra sem quebrá-la.

Perelman → "conjectura da alma" ⇒ pode-se deduzir as propriedades de um objeto matemático a partir de pequenas regiões desses objetos, chama-se alma.

Instituto Steklov em São Petersburgo

1982 – Richard Hamilton publicou um artigo sobre "fluxo de Ricci", com a qual se suspeitava ser possível comprovar a conjectura de Poincaré.

"A monetização do êxito do máximo enigma da matemática"! (Perelman).

"Se a teoria está correta, não necessita de outro tipo de reconhecimento"
Perelman.

"Não me interessa o dinheiro ou a fama. Não quero estar em exposição como um animal em um zoológico". Perelman.

20190618

12 círculos mesmo diâmetro

Áreas A1, A2 e A3 são iguais. Checar!
(rachurada)

3B + 1/2 E + 1/2 3 = 2 círculos.

2A + 1/2 C + 1/2 2 = 2 círculos.

Veja:

1 + 1A + 1B + 1/2 C + 1/2 E = 4 círculos.

D + 2B + 3A + 1/2 2 + 1/2 3 = 4 círculos.

Veja:

1A + 1/2 1 + 1/2 C = 2 círculos
1B + 1/2 1 + 1/2 E = 2 círculos

2A + 1/2 2 + 1/2 C = 2 círculos.
3B + 1/2 3 + 1/2 E = 2 círculos.

2B + 1/2 2 + 1/2 D = 2 círculos.

3A + 1/2 3 + 1/2 D = 2 círculos.

$$\operatorname{sen}\alpha = \frac{co}{h}$$

$$\cos\alpha = \frac{ca}{h}$$

$$\tan\alpha = \frac{co}{ca}$$

$$\cot\alpha = \frac{ca}{co}$$

$$\sec\alpha = \frac{h}{ca}$$

$$\csc\alpha = \frac{h}{co}$$

20190618. TCM

1

$sen = \frac{co}{h}$

$cos = \frac{ca}{h}$

$tag = \frac{co}{ca}$

$cot = \frac{ca}{co}$

$sec = \frac{h}{ca}$

$csc = \frac{h}{ca}$

Trigonometry
Cubic
Mirch

A e B são variáveis nos eixos do cos(x) → eixo x e no sen(x) → eixo y (subdivisões)

veja:

$x(\cos\theta, \sin\theta)$

sen y eixo

Ab = Bb
(eixo sen)

cos x eixo

obs: eixos sen e cos são móveis.

Triângulo A
(sen < x)
x (x, y)
y < sen(x)
y eixo y é móvel.

$\text{sen}\,\theta = \frac{CO}{R} = \frac{Ab}{Aa}$

$\cos\theta = \frac{CA}{R} = \frac{Ac}{Aa}$

$\tan\theta = \frac{CO}{CA} = \frac{Ab}{Ac}$

Triângulo B
(cos > cos △A)

$Ac + Bc < 1$
$c(1, 0)$
x y

obs:

$\text{sen}\,\gamma = \frac{CO}{R} = \frac{b}{a}$

$\cos\gamma = \frac{CA}{R} = \frac{c}{a}$

$\tan\gamma = \frac{CO}{CA} = \frac{b}{c}$

$\text{sen}\,\theta_B = \frac{CO}{R} = \frac{Bb}{Ba}$; $\cos\theta_B = \frac{CA}{R} = \frac{Bc}{Ba}$; $\tan\theta_B = \frac{CO}{CA} = \frac{Bb}{Bc}$

eixo x é móvel

20190618 TCM (2)

$Ab = Bb < 1$ (ponto sobre o círculo)

$Ab = Bb < Ba$

Usando os triângulos A e B como um triângulo apenas, teremos:

$Ab = Bb = co$ (cateto oposto)

$co + x = Ba$ (hipotenusa do ΔB)

$Ac + Bc = Ca$ (cateto adjacente)

Ficaremos:

$$\operatorname{sen}\theta = \frac{co + x}{Aa}$$

$$\cos\theta = \frac{Ac + Bc}{Aa}$$

$$\tan\theta = \frac{co + x}{Ac + Bc}$$

Important:

$Ab = Bb < 1$ (sen x)

$Ac + Bc < 1$ (cos y)

20190618 BIPOLAR COORDINATE (1)

Small Scale Deformation using advanced nanoindentation techniques. Volinsky

MDPI.com

Pág. 128 (137)

4. Discussion

4.1. The Investigation of Dislocation Nucleation and the Estimation of Peierls Stress

Pág 130 (139)

To Compute the Peach-Koehler force, shear stress field is required beneath the indenter.

(campo de tensão de cisalhamento é necessário abaixo do penetrador)

shear stress in bipolar coordinates is [24]

$$\sigma_{xy} = \pm \frac{P r^2 \sin\theta}{\pi (r_1 r_2)^{3/2}} \sin\left[\theta - \frac{3}{2}(\theta_1 + \theta_2)\right]$$

where P is the indentation load.

Figure 6. Bipolar coordinate for a 2a indentation contact.

The image force acting on one of the dislocations of a dipole of width $d=2a$ at depth h beneath the indenter can be shown to be

$$F = \frac{\mu b^2}{\pi(1-\nu)}\left[\frac{1}{4h} - \frac{4h^3(4h^2-3d^2)}{(4h^2+d^2)^3}\right]$$

According to the discussion above, Peierls stress in every size of surface pit defect has been calculated and plotted.

20190623_04/Mathematics Physical Science/Mathematics...pdf

Pdg. 619

Example 17.2.2. Branch Cuts

Veja Figure 17.2

obs: VEJA BIPOLAR COORDINATE.

obs.:

$f(z) = (z^2-1)^{1/2}$ has two branch points, at $z_1 = 1$ and $z_2 = -1$.

For further discussion it may be helpful to make the definitions

$$z - z_1 = r_1 e^{i\theta_1} \text{ and}$$

$z - z_2 = r_2 e^{i\theta_2}$, so

$$f(x) = (z - z_1)^{1/2}(z - z_2)^{1/2} =$$

$$(r_1 r_2)^{1/2} e^{i(\theta_1 + \theta_2)/2} \quad (17.4)$$

The relationships between the quantities in Eq. (17.4) are shown in Fig. 17.2.

1995 do físico Ted Jacobson, da Universidade de Maryland (EUA).

Maximização da entropia

A Ideia de Verlinde é usar o princípio de maximização da entropia para substituir a força fundamental de Newton e Einstein!

Verlinde → princípio holográfico, proposto pelo Nobel de Física holandês Gerard 't Hooft, que não por acaso orientou o mestrado de Verlinde

Este princípio sugere que as coisas tridimensionais são feitas de informação e que essa informação fica codificada em uma "superfície" bidimensional

Problem 20 →

O Produto de Wallis

$$\frac{2}{1}\cdot\frac{2}{3}\cdot\frac{4}{3}\cdot\frac{4}{5}\cdot\frac{6}{5}\cdot\frac{6}{7}\cdots\frac{2n}{2n-1}\cdot\frac{2n}{2n+1}\to\frac{\pi}{2}$$

é provado no Apêndice A.5.

Como $2n/(2n+1) \to 1$,

o produto de Wallis pode também ser escrito como

$$\frac{2^2}{3^2} \cdot \frac{4^2}{5^2} \cdot \frac{6^2}{7^2} \cdots$$

$$\frac{(2n-2)^2}{(2n-1)^2} \cdot 2n \to \frac{\pi}{2}$$

Extraindo-se raízes quadradas e multiplicando o numerador e o denominador por $2 \cdot 4 \cdot 6 \ldots (2n-2)$, deduza a fórmula

$$\lim_{n \to \infty} \frac{(n!)^2 2^{2n}}{(2n)! \sqrt{n}} = \sqrt{\pi},$$

que será necessária no Problema 21.

Se você fizer uma outra esfera com a hipotenusa de um triângulo retângulo cujo lado tem 4 unidade, teremos (cateto) uma esfera com o dobro do volume

$$(x-4)^2 + y^2 + z^2 = 32$$

20200217 0300

A realidade do ~~sistema~~ ~~Ao mundo~~ plano físico, a distância entre 2 pontos é uma reta
↳ (Euclides)

mas a realidade é curva pois a gravidade universal transforma o espaço plano em curvo.
↳ use book: Lens gravitational

Por este motivo é que não conseguimos fazer a quadratura do círculo.

Cálculo a curvatura do espaço com a massa solar e compare com as distâncias astronômicas universais, observe se há alteração na curvatura de forma geral.

Use triângulo de Pitágoras. Pluriciano e compare com a identidade trigonométrica Einsteiniana
(veja email que eu mandei!)

Este cubo não tem ângulo reto (90°)

cubo pugichiano

A(x, y, z)

B(x', y', z)

A distância entre A e B + coeficiente pugichiano = cubo pugichiano.

Obs. A folha de papel não é plana por este motivo não podemos fazer a quadratura e muito menos a prova pois estamos utilizando sistema de cálculo errado para calcular objetos diferentes que pertencem à outra realidade, a realidade da curvatura universal.

20200217

(2)

Use a curvatura gerada pela gravidade do Sol pois esta é a nossa realidade, depois simule com o restante do universo e suas implicações.

—

O círculo curvo é maior que o círculo plano idealizado (teórico) mas distorcido pela nossa percepção pois estamos estudando uma realidade com instrumentos de outra realidade.

A teoria é uma abordagem mas a realidade que estamos estudando apresenta as suas próprias peculiaridades e deve ser analisada com novos instrumentos matemáticos adequados a esta nova realidade.

A forma como se faz o cálculo deve ser conformada à realidade existente, real e sob a qual nós estamos inseridos, sendo que os conceitos teóricos do mundo plano devem ser utilizados de forma complementar e suficiente pois estes dois mundos parecem iguais mas apresentam peculiaridades que são incompatíveis, são como gêmeos univitelinos com personalidade discrepantes.
(comportamentos)

Por este motivo que Einstein não conseguiu fazer a unificação que tanto procurava.

A Física clássica e a Física Quântica coexistem mas apresentam as suas próprias realidades que devem ser analisadas e explicadas usando instrumentos matemáticos adequados à realidade de cada mundo.

Você não pode usar um óculos para longe para ler algo que se encontra perto de você e tem usar um óculos de perto para ler um mundo que se encontra distante de você. Parece algo óbvio e primário, mas nós estamos tentando descrever mundos diferentes com a mesma instrumento de cálculo, ou seja, usando a mesma matemática para realidade distintas que coexistentes mas são descritas de formas diferentes e se manifestam distintamente na realidade na qual estamos inseridos.

Portanto, água e óleo no mesmo copo duas com densidades diferentes e comportamentos distintos, ambos líquidos coexistindo no mesmo espaço mas são realidades diferentes.

20200217 0330.

2020021707 30 (3)

Deus criou a Matemática Perfeita, construiu e a chave para se conhecer o mundo e o universo, mas a imperfeição do homem tenta desvendar os seus segredos, de forma imprecisa ~~da matemática~~ e a poucos mortais foi se dado o direito de conhecê-los.

vislumbrar

criando a ciência que temos atualmente.

A água e o óleo são substâncias diferentes ~~da mesma natureza~~) coexistindo na mesma realidade, podendo interagir entre si mas nunca se misturam, (~~assim também é~~) e portanto devem ser analisados de forma independente e comparados quando necessário.

assim também é, o ~~plano~~ ~~mundo~~ sistema plano teórico e a realidade em que vivemos, o ~~mundo~~ curvo.

universo. Desta forma, estes dois sistemas são realidades distintas coexistindo em um mesmo espaço, criando cada qual uma matemática diversa da outra, interrelacionada, dependente uma da outra e sem a qual não poderíamos entender o nosso universo.

ARQ-IMPORTANT_07 / Bostes Important / Variáveis Complexas José Carlos Leite / Variáveis Complexas e aplicações - 2015.pdf

Pág. 87 (100) Chapter 3

30 A Função Exponencial

$$e^z = e^x e^{iy}$$

fórmula de Euler

(Ver Sufo 7)

$$e^{iy} = \cos y + i \operatorname{sen} y.$$

$$\left(a^{\frac{1}{n}}\right)^n = (a^n)^{\frac{1}{n}} = a$$

2ª 05/19 2R 20 min

1 hipótese

A + B = 1/4 Circunferência (Arco)
C + D = 1/4
E + F = 1/4
G + H = 1/4

2 raios = 1/4
2 raios = 1/4
2 raios = 1/4
2 raios = 1/4

∴ 8 raios = 4 arcos

1 raio = $\frac{4}{8}$ ou seja 1 raio = $\frac{1}{2}$ arco

8 raios = 1 circunferência 20090519

1 A = $\frac{1}{8}$

(1 A)

10 | 8
200 | 125
40

∴ π = 0,125
↳ este valor é μ (em Grego)

μu
(Musich)

---

o π substituí um número irracional
↳ houve mistura RAIO com este número

Porque, eu não posso substituir o π por um outro valor ou referência.

Para gasto:

O valor do arco "in abstrato" pode-se tornar-se o Mu.

(1 B)

4 Mus = 1 circunferência

$1 \text{ Mu} = \frac{1}{4}$

1 Mu = 0,25

20090519 2h28 min

2 hipótese (2)

4 círculos menores = 1 circunferência

ou com 5 círculos

2009 05 19 3R.

3 hipótese

(3)

equilátero

A = diâmetro ou 2 raios = 1/2 circunferência

2 raios = 1 arco

2 raios = 1 arco

∴

4 raios = 2 arcos ou 1 circunferência

1 raio = 2/4 = 1/2 arco

2009 05 19 3R.

3 hipótese

equilátero

o diâmetro ou 2 raios = 1/2 circunferência

equilátero

A = diâmetro ou 2 raios = 1/2 circunferência

2 raios = 1 arco

2 raios = 1 arco

4 raios = 2 arcos ou 1 circunferência

1 raio = 2/4 = 1/2 arco

Apolhonius off: $\pi = \frac{256}{81}$ Área Círculo = C

$Pi = 3 + \frac{1}{7}$

O primeiro círculo faz o seu percurso dentro do 2º no sentido horário, sendo que o seu diâmetro ($d = 2r$) é igual ao raio do 2º círculo. O diâmetro do 2º é igual ao raio do 3º círculo e assim por diante.

Usar o cálculo de área do círculo em cada porção (simulação) para compensar a inexatidão do cálculo da área de cada círculo, ou seja,

cada porção do círculo menor, dentro do maior, vai auxiliar no cálculo do círculo maior.

O percurso de cada círculo será feito em 7 porções. Portanto, o

Veja a simulação nos números pares.

Importante

Concatenar os raios e os diâmetros com os porções dos círculos dentro de cada círculo, par ou ímpar

(7) ou (6) porções

...liar no cada círculo ...o em 7 porções. Portanto o 1º círculo tem 7 porções dentro do 2º e o 3º por que não tem 7 porções etc

Na concatenação e adequação entre pares e ímpares, veja se você pode criar algum "algoritmo" ou um número fixo para compensar a imprecisão do cálculo do π.

Este número fixo é o π (MMF)

① Dictionary of Mathematics Terms.pdf

(Pag 49 (real 35))

This equation is known as the Euler-Lagrange equation.

For example, the distance along a path between the two points ~~(x=a), (y~~

$(x=a, y=y_a)$ and

$(x=b, y=y_b)$

(comes from the integral (yet arc length):

$$S = \int_a^b \sqrt{1+y'^2}\, dx$$

(Pag. 134 (120))

Euler → π for the circumference of a circle of diameter 1, and i for $\sqrt{-1}$.

→ Arc Length (Pag 29 (14))

The length of an arc of a curve can be found with integration.

Terms.pdf

the Euler-

ng a pdf

20110421

(I)

Let ds represent a very small segment of the arc, and let dx and dy represent the x and y components of the arc.

(See figure 10.)

Then:

$$ds = \sqrt{dx^2 + dy^2}$$

Rewrite this as:

$$ds = \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx$$

etc. (lec)

---

curve: lan

② Pag 127 (113)

<u>Elliptic Integral</u> $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

Pg 128 (114)

The arc length integral for the distance around the ellipse is:

$$S = 4\int_0^a \sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx$$

$$S = 4\int_0^a \sqrt{1+\frac{x^2 b^2}{a^4}\left(1-\frac{x^2}{a^2}\right)^{-1}}\,dx$$

Simplified

$$S = 4\int_0^a \sqrt{\frac{a^4+(b^2-a^2)x^2}{a^4-a^2x^2}}\,dx$$

Let K represent the eccentricity of the ellipse:

$$K^2 = \frac{a^2-b^2}{a^2}$$

Obs: O valor 2n está bem no meio entre os valores das duas casas

[Ex.: Quando 2n = 64, a diferença entre as casas anteriores e posteriores está entre 63 e 65 respectivamente, ou seja,

a casa 64, representa (n)

a casa 32 e portanto entre a casa 31 e 32, o valor é 63

e assim, entre 32 e 33, o valor é 65

Resumo:

O valor $2r$ representa o valor numérico faltante entre as diferenças entre as casas imediatamente inferior e superior ao número que deu origem ao respectivo valor $2r$.

Assim, o valor $2r = 32$ representa o valor faltante entre 31 e 33, cujos valores referem-se às diferenças entre as casas 15 e 16 e entre 16 e 17, pois 32 é o valor $2r$ e portanto, $r = 16$.

$2r$ r^2

estudo

21	42	441	41
22	44	484	43
23	46	529	45
24	48	576	47
25	50	625	49
26	52	676	51
27	54	729	53
28	56	784	55
29	58	841	57
30	60	900	59

2

→ usei a regra do triângulo e descobri o valor ao quadrado (r^2) → área do círculo, sem usar calculadora, não apenas fazendo a soma dos números subsequentes acrescen-

apenas 2 números ao número imediatamente anterior.

Detalhando:

21	42	441	→ 441 ÷ 42 =	10,5
22	44	484	→ 484 ÷ 44 =	11
23	46	529	→ 529 ÷ 46 =	11,5
24	48	576	→ 576 ÷ 48 =	
25	50	625	→ 625 ÷ 50 =	
26	52	676	→ 676 ÷ 52 =	
27	54	729	→ 729 ÷ 54 =	
28	56	784	→ 784 ÷ 56 =	
29	58	841	→ 841 ÷ 58 =	
30	60	900	→ 900 ÷ 60 =	15

Resumindo:

A razão entre $2r$ e r^2 varia de 0,5 entre uma casa e outra (progressão também constante).

Importante:

Pegue o valor do r (raio) e divida por 2

$30 \div 2 = 15$

↳ este valor é a razão entre $2r$ e r^2 deste raio.

2014 03 03

1) Circumference of circle $= 2\pi r$

2) Area of circle $= \pi r^2$

3) Volume of prism $= Ba$

4) Volume of pyramid $= \frac{1}{3} Ba$

5) Volume of right circular cylinder =

$\pi r^2 a$

6) Lateral surface of right circular cylinder =

$2\pi r a$

7) Total surface of right circular cylinder =

$2\pi r(r+a)$

8) Volume of right circular cone =

$2\pi r(r+a)$

9) Lateral surface of right circular cone =

$\pi r s$

10) Total surface of right circular cone =

$$\pi r(r+s)$$

11) Volume of sphere $= \frac{4}{3}\pi r^3$

12) Surface of sphere $= 4\pi r^2$

obs.: r = radius

a = altitude

B = area of base

s = slant height.

or h

Cylinder: vol $= \pi r^2 h$

lateral area $= 2\pi r h$

Total surface area $= 2\pi r h + 2\pi r^2$

Cone:

$$\text{vol} = \pi r^2 h / 3$$

lateral area $= \pi r \sqrt{r^2 + h^2}$

Total surface area $= \pi r \sqrt{r^2 + h^2} + \pi r^2$.

Sérgio Musich 15 (02/14/001)

2015 02/14 11h30min

Source: 20150213_Raz_2_até10_009_003_008.ggb

circle c_2: $(x-0.5)^2 + (y-0.5)^2 = 0.25$

Ponto M_2 (Point M_2) = intersection point of c_2, g_2

g_2: $(x-2.5)^2 + (y-2.5)^2 = 6.25$

(5: circle)

Creating circle c_2:

create line com Angle bisector of c, a, ou seja, divida a hipotenusa de um triângulo retângulo por dois ($\sqrt{2}/2$).

Crie o ponto $\underline{\underline{V}}$ (0,5, 0.5)

Deste ponto: crie circle c_2

crie o point H_1 sobre o eixo y onde haja intersect com o circle c_2

$H_1 = (0, 0.5)$

↳ mesma posição de y em relação V e M_2

atente-se ao mesmo alinhamento em y

(criação do primeiro circle)

Passemos para a segunda fase:
o primeiro triângulo retângulo

com base neste criemos vários polígonos com espaçamento de

1 em 1 cm.

ao final:

pine t_1 = angle bisector of x, a

(use o primeiro triângulo por base)

Use os pontos (intersection) da linha t_1 com os segmentos de reta de cada polígono subsequente

Portanto, houve uma divisão ao meio de todos os segmentos de retas subsequentes

No caso do primeiro triângulo:

$$\frac{\sqrt{2}}{2}$$

Ou seja,

$ca = \sqrt{2}$ (hipotenusa)

Portanto:

$ca = cV + Va$

15 (02/14/003)

CV e CA = 0.7071067811186548

A soma dos dois = $\sqrt{2}$

Em relação ao segundo polígono ACDE com valor 2 (x e y), fizemos o seguinte:

triângulo retângulo ABC + polígono ACDE =

triângulo retângulo EBD com 2 cm de arestas cada.

Desta forma, este mesmo princípio serve para todos os demais polígonos subsequentes, criando-se, assim, triângulos retângulos cada vez maiores.

Importante:

O primeiro triângulo 1 cm, gera como resultado a hipotenusa $\sqrt{2}$ e a linha tg → angle bisector com dois segmentos de reta com tamanho $\frac{\sqrt{2}}{2}$.

Em relação ao segundo triângulo, (2 cm)
os dois segmentos unidos tem o tamanho de $\sqrt{2}$, ou seja, a hipotenusa tem $2\sqrt{2}$.

Deste estudo preliminar, podemos observar que: (2m)

1) primeiro triângulo (1 cm) unir 2 segmentos de reta com tamanho $\frac{\sqrt{2}}{2}$, ou seja, (cada)

0,707106781186548...

dobro

2) segundo triângulo (2 cm) unir 2 segmentos de reta com tamanho $\sqrt{2}$, ou seja,

→ 1.414213562373095... (cada)

3) terceiro triângulo (3 cm)

2 segmentos = a soma dos segmentos de reta do 1º e 2º triângulos

Desta forma:

$\frac{\sqrt{2}}{2} + \sqrt{2} = \frac{1}{2}$ hipotenusa do 3º triângulo

15 02/14/004

4) quarto triângulo (4 cm)

2 segmentos → $2\sqrt{2}$ (cada), ou seja,

2.828427124746 19...

5) quinto triângulo (5 cm)

2 segmentos → $2\sqrt{2} + \frac{\sqrt{2}}{2}$ (cada), ou seja,

3.535533905932738...

6) 6 cm →

4.242640687119285...

7) 7 cm →

4.949747468305833

8) 8 cm →

→ 5.656854249492381 (dobro de $2\sqrt{2}$),

ou seja,

$4\sqrt{2}$

Em geral, houve um acréscimo

de $\frac{\sqrt{2}}{2}$ para cada avanço no polígono subsequente.

Projeção: $\left(\frac{\sqrt{2}}{2} \to \sqrt{2}\right)$

a) triângulo 1 p/ 2 → dobra o valor de cada segmento;

b) triângulo 3 → acréscimo $\frac{\sqrt{2}}{2}$;] intervalo

c) triângulo 4 → $2\sqrt{2}$;

d) triângulo 5 → $+\frac{\sqrt{2}}{2}$;

e) triângulo 6 → $+\frac{\sqrt{2}}{2}$;

f) triângulo 7 → $+\frac{\sqrt{2}}{2}$;

] 3 períodos de espera (intervalo)

g) triângulo 8 → $2\sqrt{2} \cdot 2 =$ de 4

$4\sqrt{2}$

Obs: De acordo com a projeção para que se efetue a duplicação do valor de $\sqrt{2}$, devemos observar a periodicidade em que isto

acontece.

(1) intervalo de espera $a \to 1p/2$ (dobra)

$\to b$ (3) triângulo

Assim,

no terceiro triângulo somente haverá um incremento de $\frac{\sqrt{2}}{2}$

No 4º triângulo $\to 2\sqrt{2}$

Próximo intervalo:

(3) acréscimos de $\frac{\sqrt{2}}{2}$ | 5, 6, 7 triângulos

obs.:

Assim, no 8º triângulo obteremos $4\sqrt{2}$, ou seja,

5,6568542494923 81...

Vejamos a evolução (projeção):

acréscimo $\frac{\sqrt{2}}{2}$

tilibra

9º triângulo →

6.36396103067892 8...

10º triângulo →

7.071067811865476...

11º triângulo →

7.778174593052022...

12º triângulo →

8.485281374238 57...,

ou seja, $6\sqrt{2}$

<u>Em resumo</u>:

triângulos

$1 \rightarrow 2 = \frac{\sqrt{2}}{2} \rightarrow \sqrt{2}$

$3 = \sqrt{2} + \frac{\sqrt{2}}{2}$

$4 = \left(\sqrt{2} + \frac{\sqrt{2}}{2}\right) + \frac{\sqrt{2}}{2} =$

15 02/24/006

$2\sqrt{2}$

$$5 = 2\sqrt{2} + \frac{\sqrt{2}}{2}$$

$$6 = \left(2\sqrt{2} + \frac{\sqrt{2}}{2}\right) + \frac{\sqrt{2}}{2} = 3\sqrt{2}$$

$$7 = \left[\left(2\sqrt{2} + \frac{\sqrt{2}}{2}\right) + \frac{\sqrt{2}}{2}\right] + \frac{\sqrt{2}}{2}$$

$$\left[\left(2\sqrt{2} + \sqrt{2}\right)\right] + \frac{\sqrt{2}}{2}$$

$$2\sqrt{2} + \sqrt{2} + \frac{\sqrt{2}}{2} = 3\sqrt{2} + \frac{\sqrt{2}}{2}$$

$$8 = \left(\underbrace{2\sqrt{2} + \sqrt{2} + \frac{\sqrt{2}}{2}}_{3\sqrt{2}}\right) + \frac{\sqrt{2}}{2}$$

$$2\sqrt{2} + \sqrt{2} + \sqrt{2} =$$

$$4\sqrt{2}$$

$$9 = 4\sqrt{2} + \frac{\sqrt{2}}{2}$$

$$10 = \left(4\sqrt{2} + \frac{\sqrt{2}}{2}\right) + \frac{\sqrt{2}}{2} = 4\sqrt{2} + \sqrt{2} =$$

$$5\sqrt{2}$$

$$11 = 4\sqrt{2} + \sqrt{2} = 5\sqrt{2} + \frac{\sqrt{2}}{2}$$

$$12 = (4\sqrt{2} + \sqrt{2}) + \frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}$$

$$5\sqrt{2} + \sqrt{2} =$$

$$6\sqrt{2}$$

Assim:

$$11 = 5\sqrt{2} + \frac{\sqrt{2}}{2}$$

$$12 = \left(5\sqrt{2} + \frac{\sqrt{2}}{2}\right) + \frac{\sqrt{2}}{2} =$$

$$5\sqrt{2} + \sqrt{2} =$$

$$6\sqrt{2}$$

Resumo:

Triângulo $2 \rightarrow \sqrt{2}$

$4 \rightarrow 2\sqrt{2}$

$6 \rightarrow 3\sqrt{2}$

$8 \rightarrow 4\sqrt{2}$

$10 \rightarrow 5\sqrt{2}$

$12 \rightarrow 6\sqrt{2}$

15 (02/14/007)

Circles:

$\overline{AB} = \overline{BC} = \overline{CD} = 0.20710678118654 8\ldots$

(sempre a mesma distância)

Important:

$\overline{AB} + \overline{BC} = 0.41421356237309 5$

$= \sqrt{2} - 1$

Obs.:

A soma do mesmo valor de forma continuada (progressivamente), obtemos os valores próximos aos segmentos de reta decorrentes do uso line T_1, ou seja, Angle bisector of $\angle_1 a$ (referente ao primeiro triângulo)

↳ arestas = 1 cm

hipotenusa = $\sqrt{2}$

segmentos de reta = $\frac{\sqrt{2}}{2}$

Ff:

Vejamos o que obtemos:

a) $1,4149 \cong \sqrt{2}$ $(1,4142...)$

b) $2,8\cancel{89}9 \cong 2\sqrt{2}$ $(2,828...)$

OK

15/02/14/008

Obs.: Erro existente

a) 1,449 para 1,414 → $\frac{35}{1000}$

0,035

b) 2,899 para 2,828 → $\frac{71}{1000}$

0,071

Important:

Os segmentos $\overline{AB} + \overline{BC} =$

0,4142135623730950

representa exatamente

$\sqrt{2} - 1$

Partindo-se desta preliminar observação de relevante importância e análise futura, podemos passar para uma próxima fase de sondagem.

Nós começaremos com o desencadeamento de informações decorrentes da análise do círculo

Circle C_2 (0.5 cm raio).

$a \neq b$

Angle bisector of r, a

Obs. Neste caso os segmentos obtidos são exatamente do mesmo comprimento.

Usando este mesmo procedimento, a sistemática não se aplica, criando-se segmentos de retas diferentes.

$a \neq b$

$\overline{WN_2} = a \Rightarrow 0.5857864376269 05$

$\overline{N_2E} = b \Rightarrow 0.828427124746 19$

Para resolvermos a questão, nós deveremos utilizar o conceito Perpendicular Bisector $\overline{WE}$

Esta opção cria na realidade uma reta paralela ao primeiro (angle bisector).

Encontre o ponto $\underline{O_2}$

Portanto:

$WO_2 = 0.7071067811865 48 = \sqrt{2}$

$O_2E = \sqrt{2}$

Obs.:

A distância entre N_2 e O_2 = 0.12132034355964 3

Posteriormente, nós criaremos uma nova Perpendicular Bisector of BW com point $\underline{V}$.

Desta forma, nós teremos um quadrado, ou seja, um polígono regular, que estará conectado com o circle C_2 com 1 vértice no centro do referido

tilibra

Circle.

Nós temos Quadrilateral:

Polygon A, V, W, O_2

obs: Perimeter $2\sqrt{2}$, ou seja, $2.828427124746 19$

Perpendicular Bisector V, W

Perpendicular Bisector W, O_2

O Ponto M_2 é a intersecção das 2 retas criadas anteriormente.

Este ponto M_2 faz também intersecção com o circle c_2

15/02/14 010

A linha criada pela Perpendicular Bisector of W E ($\overline{WE}$) faz a intersecção com o eixo $\underline{x}$ no point $\underline{\underline{1}}$ (A) e no ponto $\underline{K_2}$.

K_2 ⇒ Intersection point of d_2 (circle), r_2 →

↳ Circle through C with center $\underline{\underline{W}}$

Circle through J with center G_1

<u>obs</u>.: Pelo ponto K_2 passa também (intersecção) o segmento de reta F, G ($\overline{FG}$) do Quadrilateral E, D, F, G.

O Ponto K_2 (2, 1)

Voltando às medições:

$\overline{A_2K_2} = \frac{\sqrt{2}}{2}$, ou seja,

0.7071067811865 48.

Vejamos:

$\overline{O_2K_2} = 0.7071 = \frac{\sqrt{2}}{2}$

$\overline{AK_2} = 1.41421356... = \sqrt{2}$

$\overline{AV_2} = 1$

$\overline{V_2K_2} = 0.41421356... = \sqrt{2} - 1$

$\overline{N_2V_2} = 0.3170253355622 14$

$\overline{N_2O_2} = 0.12132034355 9643$

$\overline{O_2V_2} = 0.2928932188 13452$

$\overline{AO_2} = 0.707106\ldots = \frac{\sqrt{2}}{2}$ 15 (02/14/011)

$\overline{AO_2} + \overline{O_2V_2} = 1 \; (= \overline{AV_2})$

Outras informações:

$V_2O_2N_2$ = perímetro =

0.7312388979353 09

Fazer estudo:

$\frac{\sqrt{2}}{5} = 0.2828427124746 19$

Obs:

$2.828427124746 19 \div 10 = 0.2828$

$(2\sqrt{2})$

Portanto: $\frac{\cancel{2}\sqrt{2}}{\cancel{10}\,5} = \frac{\sqrt{2}}{5}$

Informações Complementares:

Circle d_2

↳ circle through C with center W

Area of $d_2 = \pi$

<u>Function</u>:

$d_2 : (x-1)^2 + (y-1)^2 = 1$

<u>obs</u>.:

Quadrilateral poly 11:

A, V, W, O_2

observamos 4 arestas com o comprimento $\frac{\sqrt{2}}{2}$

Perimeter: 2.828..., ou seja,

$2\sqrt{2}$

<u>Extrapolação</u>:

Copiando-se o mesmo quadrado em O_2, W, Z, K_2, idêntico ao anterior,

nós observaremos que ambos os quadrados estão inscritos no circulo d_2.

Outros aspectos:

Circle c_2 (0.5 cm) →

obs

$\overline{VW} = \frac{\sqrt{2}}{2}$

4 arestas com $\frac{\sqrt{2}}{4}$ (cada)

Important: (Area

Obs.:

poly12 = 0.017766952966369

poly13 = 0.004441738241592

poly14 = 0.207106781186547

Important:

O valor = a distância entre $\overline{AB}$

Portanto:

poly 12 = poly 13 x 4

poly 14 = poly 13 x 46.62741699

Outro Aspecto:

poly 14 = 0.207106781186547

O valor em questão aparece em vários aspectos no gráfico em análise.

Estudo:

$\frac{1}{x} = y \quad x = 0.207106781186547$

$y = 4.828427124746202323331799 5280387$

Obs.:

$\sqrt{2} = 1.414213562373095048801688724 2097$

$\times 2 = 2.828427124746190097603377448 4194$

Portanto: $2\sqrt{2} + 2 = y$

Important:

Fazer análise do que obtivemos com o novo arquivo abaixo:

20150219_Pentagrama_inscrito_circulo_padrão_001_001.ggb

Vejamos:

Poly 1 = Pentagrama

Poly 3 = hexagono → ano Heptágono

Os referidos polígonos estão a uma

distância de 3 com um do outro sobre o eixo X (X AXIS):

Area:

Poly 03 ⇒ 3.633912444001587

Poly 01 ⇒ 1.720477400588967

$$\frac{\text{Poly 03}}{\text{Poly 02}} = 2.112153546892041861141352267207 4$$

Important:

Partindo-se do hexágono e traçando

Line d_1: Perpendicular Bisector of NO

observamos

que a linha passa pelo centro do hexágono e no seu prolongamento, constatamos que a referida linha passa pelo ponto A do pentagrama.

olhando em detalhes, não passa pelo ponto A, porque não é

o dobro exatamente a área deles um em relação ao outro.

Solução do Problema em questão:

1) Análise da questão:

Estamos fazendo uma correlação direta entre um pentagrama e um hexágono. Eles são elementos distintos e com configurações próprias, naturezas diferentes sobre um mesmo plano.

Vamos utilizar estas diferenças para entender o comportamento em relação à área e perímetros dos referidos elementos em questão.

a) Perímetro: 5 cm
Área: 1.7204... } Pentagrama

b) Perímetro: 7 cm
Área: 3.633... } Heptagrama

Importante:

Observamos que o ponto de intersecção sobre o eixo Ox é exatamente

no ponto $\Rightarrow S$

$x \rightarrow -0.048917339522304$

$y \rightarrow 0$

—

Obs.: Point S: intersection point of d_1, x Axis.

—

Vamos fazer a simulação com um hexágrama.

Compararemos a área e o perímetro.

Fermat Last Theorem

16 (04/08/001)

$x^2 + y^2 = z^2$

$x^3 + y^3 \neq z^3$ (?)

$x^{3.14} + y^{3.14} \neq z^{3.14}$ (?)

obs:

$2^{1.14} = 2.20381023175$

Imp:

$\exp(1,14) = 3,126768 \cong \pi$.

$\exp(2) = 7.38$

$\hookrightarrow \times 2 = 6,25...$

Vejamos:

$2^2 + 3^2 = 4^2 \Rightarrow 4 + 9 = 16$ (ok)

$2^3 + 3^3 = 4^3 \Rightarrow 8 + 27 \neq 64$

$\vee$

35

obs: $64 - 100$

$35 - x \Rightarrow 64x = 3500$

$x = \frac{3500}{64}$

$x = 54,6875$

tilibra

$\sqrt[3]{35} = 3{,}27106631019.$

Important:

$$\boxed{\begin{matrix}1^3\\1\end{matrix}} + 2^3 = 3^3$$

$$1 + 8 \neq 27$$

$8 \to 9 \to \times 3$

Analisemos 1^3:

$$2^3 = 2 \times 2 \times 2 = 8$$

$= 6$ $\neq$

outro lado:

$= 4 \quad (2^2)$

$= 8 \quad (2^3)$

$= 16 \quad (2^4)$

16 04/08/002

Seguindo o mesmo raciocínio:

$$1^3 = 1 \times 1 \times 1 = 1$$

$$\square + \square + \square = 3$$

obs.:

$$\square + \square = 2 \quad (1^2)$$

$$\square\square + \square = 3 \quad (1^3)$$

ou

$$\square + \square = 2 \quad (1^2)$$

$$\square\square + \square\square = 4 \quad (1^3)$$

estudar

Outra análise.

$$2^2 = 2 \times 2 = 4$$

Portanto:

$$A \xrightarrow{A1} A \times A' = 1$$

$$A \xrightarrow{A2} A \times A'' = 1$$

$$B \xrightarrow{B1} B \times B' = 1 \quad +$$

$$B \xrightarrow{B2} B \times B'' = 1$$

$$4 \text{ (OK)}$$

$$2^3 = 2 \times 2 \times 2 = 8$$

$$\times 2 = 8$$

4

$+$

4

Resumo:

$\rightarrow AA' \times 2 = 4$ (uno)

Melhor ainda:

16 (04/08/003)

(Conf. p/ $16 \to 2^4$)

Vejamos:

$A + A' + C + C'$

$A + A' + D + D'$

Conexão:

$A A' C = 1$

$A A'' C = 1$

$A A' D = 1$

$A A'' D = 1$

$B B' C = 1$

$B B'' C = 1$

$B B' D = 1$

$B B'' D = 1$

Outra formatação: (simplificando)

$$\begin{matrix} \boxed{A} & & \boxed{C} & & \boxed{E} \\ & \times & & \times & \\ \boxed{B} & & \boxed{D} & & \boxed{F} \end{matrix}$$

$A + C + E \rightarrow 1$

$A + C + F \rightarrow 1$

$A + D + E \rightarrow 1$

$A + D + F \rightarrow 1$

$B + C + E \rightarrow 1$

$B + C + F \rightarrow 1$

$B + D + E \rightarrow 1$

$B + D + F \rightarrow 1$

/8

Vamos aplicá-la ao $1^3 \Rightarrow$

$1^3 = 1 \times 1 \times 1 = 1$

Usando-se da mesma lógica (anterior)

16 04/08/004

$\boxed{A}$ $\boxed{B}$ $\boxed{C}$

1^1 1^2 1^3

$A + B \longrightarrow 1$

$A + B \longrightarrow 1$

$B + C \longrightarrow 1/3 \neq 1$

Vejamos:

Se você multiplica $2 \times 2 = 4$

Se você multiplica 1 por ele (1) =

teremos 2 (soma)

Não é 1 pozinho, pois continua sendo 1.

$\therefore$ $1 \times 1 = 1 + 1 = 2$

$2 \times 2 = 2 + 2 = 4$

mesma regra

Devemos destruir a regra $1 \times 1 = 1$ //

Aprofundando:

$$2^3 = 2 \times 2 \times 2 = 8$$

$$4 \times 2 = 8$$

$$1^3 = 1 \times 1 \times 1 = ?$$

Vejamos:

$$1^1 = 1$$

$$1^2 = 2 \Rightarrow 1^2 = 2 \times 1 = 2 \ (?)$$

Será?

Pode ser. Veremos

ou

$$1^1 = 1$$

$$1^2 = 2$$

$$1^3 = 3 \Rightarrow 1 \times 1 \times 1 = 3$$

$$1 + 1 + 1 = 3$$

Se aplicarmos com relação ao nº 2 ⇒

tilibra

16 (04/08/005)

$2^1 = 2$

$2^2 = 4$

$2^3 = 8 \Rightarrow 2 \times 2 \times 2 = 8$

já não se aplica

$2 + 2 + 2 = 6$

Porquê?

$2 \times 2 = 4 \times 2 = 8$ (pega-se o valor anterior e multiplica-se por 2).

Vejamos:

$1^1 = 1$

$1^2 = 2 \Rightarrow 1 \times 1 = 2$ $(1+1=2)$

$1^3 = 2 \times 1 = 2$

$1^4 = 2 \times 1 = 2$

Aplicando-se ao 2 →

$2^1 = 2$

$2^2 = 4 \Rightarrow 2 \times 2 = 4$ ou $2 + 2 = 4$

$2^3 = 8 = 4 \times 2 = 8$

formula exp.

correlação

correlação

Retrocedendo um pouco:

$\boxed{A}$ $\boxed{B}$ $\boxed{C}$

$A + B = 1$

$A + C = 1$

$B + C = 1/3$ Será? Pode ser!

Outra hipótese: (número 1)

$\boxed{A}$ $\boxed{B}$ $\boxed{C}$

$A + B = 1$

$A + C = 1/2$ (?)

$\therefore$

$1^1 = 1$

$1^2 = 2$ (será?) Vejamos:

$\boxed{A}$ $\boxed{B}$ $\boxed{C}$

$\underbrace{A + B}_{X} = 1 \times C = 2$

(valores anteriores X C).

Pensando:

$1^3 = 1 \times 1 \times 1 = 1$ (será?)

$1^3 = 1 + 1 + 1 = 3$

$\boxed{A}\ \boxed{B}\ \boxed{C}$

$$\begin{cases} A + B = 1 \\ A + C = 1 \\ B + C = 1 \end{cases}$$

ou

$A + B = 2 \Rightarrow 1^2 = 2$

$[(A + \underline{B) - B}] + C = 2 \Rightarrow 1^3 = 2$

(X)

Confere com a página anterior 005):

Vamos ver com o número 2:

$2^3 = 2 \times 2 \times 2 = 8$

$2^3 = 2 + 2 + 2 = 6$ $\neq$

Aplicando o pensamento (anterior)

A	B	C
2	2	2

$A + B = 4 \times C = 8$
(2)

1	1	1

$A + B = 1 + 1 = 2 \times 1 = 2$

Mesmo procedimento matemático

Portanto:

Soma no primeiro termo (A + B) e multiplicação nos termos subsequentes.

Theory of geometrical construction

The proof of the irrationality of $\sqrt{2}$, as indicated by Aristotle and in "Elements" (X, 1 15), could be so interpreted that the diagonal of a given square ~~root~~ cannot be transferred towards one side by means of a purely linear operation.

...

algebraic solution → this was basically accomplished by Gauss, and the actual theory of geometrical constructions started with him.

Import:

In 1593 Vieta crowned his Supplementum geometriae with the proof that all problems that lead to equations of third or fourth degree become solvable if we, apart from compass and straightedge, allow instruments with which one can extract the third root of given quantities and trisect every angle.

Did Vieta know of the geometrical interpretation of complex algebra in Gauss's "complex number plane"?
⟹ Illus. 7.3.1
↳ Pag. 411 (424) ⟸ ✡

Pag. 412 (425) –

Algebraization of the theory of geometrical construction

Gauss ⇒ due to his discovery that the regular 17-gon can be constructed with compass and straightedge. (30/03/1796).

Further entries indicate that he came back to questions of circle division again and again, reduced to purely algebraic questions by using complex numbers, for the equation $x^n = 1$ (and/or after separating the trivial factor $x-1$ from $x^n - 1$) for which n the equation $1 + x + \dots x^{n-1} = 0$ can be solved by quadratic radicals

Pág. 413(426) – If angle trisection would be generally possible with compass and straightedge, then such is also the case in which the given angle is 60 degrees...

The third famous ancient problem, squaring the circle, leads to an investigation, under the new circumstances if number π is the root of a polynomial equation solvable by quadratic radicals.

Lambert showed the irrationality of π in 1767.

Ferdinand Lindemann finally generalized the idea of proof in 1882, i.e., he proved the transcendence of π meaning that π cannot at all be the solution of any algebraic equation with rational coefficients.

Impossibility of doubling the cube with compass and straightedge

Show by means of case-by-case analysis x^3-2 cannot be written as $(ax^2+b)(cx+d)$ with integers a, b, c, d. According to Gauss's general theory, it ~~(following)~~ follows that doubling the cube by means of compass and straightedge is impossible.

Pag. 481(494) Problem 7.3.5 *

Equivalence of construction problem in space

1. A point can be constructed by means of given points iff (if and only if) we can construct its three coordinates with compass and straightedge by means of the coordinates of the given points in an auxiliary plane regarding a given spatial Cartesian coordinate system.

Problem 7.3.6*: Torricelli point of 5 points of the plane and 4 points in space respectively

Gauss

Look:

Pág. 482(495) – Illus 7.10.2 ✱

Pág. 483(496) – Problem 7.4.1

Tractrix and Gaussian curvature of the pseudo-sphere.

Gaussian curvature is negative and constant.

Problem 7.5.1 → Constructions in Poincaré's model of the plane hyperbolic geometry. !

1. Straight connection of two points P_1, P_2 (thereby, the case that the (desk mode)

Euclidean connecting line is perpendicular to a is trivial).

2. Marking out a line segment on a point
(Take into (lesser ext.) account that reflections are generally realised by transformation by means of reciprocal radii at the relevant circle).

3* Construction of a circle with given centre and radii
(Use the solution to 2. as a "sub-program"!)

4* Prove that trisecting any angle cannot also be done with compass and straightedge in hyperbolic geometry by using the preservation of angles of Poincaré's model.
(Solution in [Schreiber 1984], chap. 2.6).

5º Postulado Euclides

Si una recta corta a otras (otras) dos formando ángulos internos por el mismo lado que suman menos de dos ángulos rectos, esas dos rectas prolongadas indefinidamente se cortarán por ese lado en que los ángulos suman menos de dos rectos.

Important:

https://echo.mpiwg-berlin.mpg.de/content/mathematics/mathematics/

Adrien Marie Legendre

20200822

$x^2 + y^2 = 1$ (Wrong!!!)

$x^2 + y^2 = 4$

$\therefore$

$1^2 = 2$

$a^2 + b^2 + c^2$

$1 = \sqrt{a^2 + b^2}$

$\Downarrow$

$a^2 + b^2$

$1^2 + 1^2 = \sqrt{2}$

$\neq$

$1 = \sqrt{2}$ (wrong!!!)

Vejamos:

$? = \sqrt{a^2 + b^2}$

$\sqrt{1^2 + 1^2}$

$\sqrt{2 + 2}$

$2 = \sqrt{4}$

e não 1!!! fera...!!!!

Correto!!!

$1^2 = 2$ pois $2^2 = 4$

(seguindo-se o mesmo princípio de cálculo)

Vejamos Radian!

$s = r$ (wrong!!!)

É um triângulo retângulo

Triângulo pitagórico:

3, 4, 5

Mas:

Vejamos a proporção:

$\frac{1}{3} + \frac{1}{4} = \frac{4+3=7}{12}$ $\frac{}{12}$

70 | 12
100 | $0{,}58\overline{3}$
040
04

0,87 - 100
1 - x

$0{,}87x = 100$
$x = \frac{100}{0{,}87}$

10000 | 0,87
130 | 114,9
430
800
17

0,5 - 100
0,87 - x

$0{,}5x = 87$
$x = \frac{87}{0{,}5}$

870 | 0,5
37 | 174 %
20

74% a mais

Outras observações:

$? = \sqrt{a^2+b^2}$
$? = \sqrt{2^2+2^2}$
$? = \sqrt{4+4}$
$? = \sqrt{8}$

Pecar!!! no mesmo triângulo

retas

$a \nparallel b$ → não são paralelas

$a \parallel c$ - são paralelas.

$3^2 + 4^2 = 5^2$

$9 + 16 = 25$

$25 = 25$

Calcular o ângulo da hipotenusa do triângulo pitagórico sobre o eixo x (cateto θ).

curvando-se este triângulo pitagórico sobre uma superfície curva até que a reta b fique paralela às retas a, c.

Calcule a curvatura do eixo x (função) (eixo curvilíneo x) no seado ponto em

que as 3 retas fiquem paralelas.

Calcule também:

o ângulo da reta d em relação ao eixo y

nas 2 configurações:

a) cartesiana (x, y)

b) curvilínea meridiana. (x_m, y_m)

2020 0822 0245

Simule a função curvilínea até o ponto em que esta se iguala à equação $x^2 + y^2 = 1$ ou 4.

o eixo x faça o mesmo traçado da equação $x^2 + y^2 = 1$ ou 4 (circunferência)

veja se as quatro retas estão em paralelo.

$x^2 + y^2 = 1$ ou 4

$a^2 + b^2 = r^2$

$\underbrace{1^2 + 1^2}_{4} = r^2 = r^2 = 4$

$r = \sqrt{4}$

$r = 2$

$\sqrt{0,5} =$

$0,70710678...$

vejamos

$0,25 \times 2 = 0,50$

$0,25 \times 0,25 =$

$0,0625$

Analisando

$(0,5)^{\wedge 2} + 0,5^{\wedge 2} + 0,5^{\wedge 2} + 0,5^{\wedge 2} = 1$

$0,5)^{\wedge 2} = 0,25$

$$\begin{cases} 0,25 + 0,25 + 0,25 + 0,25 = 1 \\ x^2 + y^2 = 4 \end{cases}$$

$1 + 1 + 1 + 1 = 4$

$2^1 + 2^1 = 4$

$\downarrow$

$x^2 + y^2 = 4$

$(\sqrt{2})^2 + (\sqrt{2})^2 = 4$

vejamos

$0,5 \times 0,5 = 0,25$

$0,5 \times 0,5 = 0,25$

$0,5 \times 0,5 = 0,25$

$0,5 \times 0,5 = 25$

$(4 \times)$

obs $\frac{1}{\sqrt{2}} = 0,70710678 = \sqrt{0,5}$

$$\begin{cases} 0{,}5 + \dfrac{1}{\sqrt{2}} = 1{,}20710678 \\ 0{,}5 + 1\sqrt{2} = 1{,}91421356 \end{cases}$$

diferencia $\sqrt{0{,}5}$

$$1 + 1 + 1 + 1 = 4$$

$0{,}5 + 0{,}5$

$(0{,}5)^2 + (0{,}5)^2$ $\quad$ $(0{,}5)^2 + (0{,}5)^2$

$0{,}25 + 0{,}25$ $\quad$ $0{,}25 + 0{,}25$

> 4

$a^2 + b^2$

16 partes (0,25)

8 partes (0,5)

$(0{,}5)^2 \times 8$

Recalculando:

Veyamos

$(0,5)^2 + (0,5)^2 + (0,5)^2 + (0,5)^2 \Rightarrow$ A

$0,25 \quad 0,25 \quad 0,25 \quad 0,25 = 1$ +

$(0,5)^2 + (0,5)^2 + (0,5)^2 + (0,5)^2 \Rightarrow$ B

$(0,5)^2 + (0,5)^2 + (0,5)^2 + (0,5)^2 \Rightarrow$ C

$(0,5)^2 + (0,5)^2 + (0,5)^2 + (0,5)^2 \Rightarrow$ D

$a^2 + b^2 + c^2 + d^2 = 1$ 4

$\times 4 = 4$

ou

$1^4 = 4$

Norma do Partido Trotskista

A lealdade do sujeito ao partido não depende do que ele recebeu do partido mas do que ele deu ao partido.

O capitalista comanda o processo revolucionário (por causa do $/$).
